ABSTRACT

Background

Postoperative nausea and vomiting (PONV) is a common adverse effect of anaesthesia and surgery. Up to 80% of patients may be affected. These outcomes are a major cause of patient dissatisfaction and may lead to prolonged hospital stay and higher costs of care along with more severe complications. Many antiemetic drugs are available for prophylaxis. They have various mechanisms of action and side effects, but there is still uncertainty about which drugs are most effective with the fewest side effects.

Objectives

• To compare the efficacy and safety of different prophylactic pharmacologic interventions (antiemetic drugs) against no treatment, against placebo, or against each other (as monotherapy or combination prophylaxis) for prevention of postoperative nausea and vomiting in adults undergoing any type of surgery under general anaesthesia

• To generate a clinically useful ranking of antiemetic drugs (monotherapy and combination prophylaxis) based on efficacy and safety

• To identify the best dose or dose range of antiemetic drugs in terms of efficacy and safety

Search methods

We searched the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, Embase, the Cumulative Index to Nursing and Allied Health Literature (CINAHL), the World Health Organization International Clinical Trials Registry Platform (WHO ICTRP), ClinicalTrials.gov, and reference lists of relevant systematic reviews. The first search was performed in November 2017 and was updated in April 2020. In the update of the search, 39 eligible studies were found that were not included in the analysis (listed as awaiting classification).

Selection criteria

Randomized controlled trials (RCTs) comparing effectiveness or side effects of single antiemetic drugs in any dose or combination against each other or against an inactive control in adults undergoing any type of surgery under general anaesthesia. All antiemetic drugs belonged to one of the following substance classes: 5-HT_3 receptor antagonists, D_2 receptor antagonists, NK_1 receptor antagonists, corticosteroids, antihistamines, and anticholinergics. No language restrictions were applied. Abstract publications were excluded.

Data collection and analysis

A review team of 11 authors independently assessed trials for inclusion and risk of bias and subsequently extracted data. We performed pair-wise meta-analyses for drugs of direct interest (amisulpride, aprepitant, casopitant, dexamethasone, dimenhydrinate, dolasetron, droperidol, fosaprepitant, granisetron, haloperidol, meclizine, methylprednisolone, metoclopramide, ondansetron, palonosetron, perphenazine, promethazine, ramosetron, rolapitant, scopolamine, and tropisetron) compared to placebo (inactive control). We performed network meta-analyses (NMAs) to estimate the relative effects and ranking (with placebo as reference) of all available single drugs and combinations. Primary outcomes were vomiting within 24 hours postoperatively, serious adverse events (SAEs), and any adverse event (AE). Secondary outcomes were drug class-specific side effects (e.g. headache), mortality, early and late vomiting, nausea, and complete response. We performed subgroup network meta-analysis with dose of drugs as a moderator variable using dose ranges based on previous consensus recommendations. We assessed certainty of evidence of NMA treatment effects for all primary outcomes and drug class-specific side effects according to GRADE (CINeMA, Confidence in Network Meta-Analysis). We restricted GRADE assessment to single drugs of direct interest compared to placebo.

Main results

We included 585 studies (97,516 randomized participants). Most of these studies were small (median sample size of 100); they were published between 1965 and 2017 and were primarily conducted in Asia (51%), Europe (25%), and North America (16%). Mean age of the overall population was 42 years. Most participants were women (83%), had American Society of Anesthesiologists (ASA) physical status I and II (70%), received perioperative opioids (88%), and underwent gynaecologic (32%) or gastrointestinal surgery (19%) under general anaesthesia using volatile anaesthetics (88%).

In this review, 44 single drugs and 51 drug combinations were compared. Most studies investigated only single drugs (72%) and included an inactive control arm (66%). The three most investigated single drugs in this review were ondansetron (246 studies), dexamethasone (120 studies), and droperidol (97 studies).

Almost all studies (89%) reported at least one efficacy outcome relevant for this review. However, only 56% reported at least one relevant safety outcome.

Altogether, 157 studies (27%) were assessed as having overall low risk of bias, 101 studies (17%) overall high risk of bias, and 327 studies (56%) overall unclear risk of bias.

Vomiting within 24 hours postoperatively

Relative effects from NMA for vomiting within 24 hours (282 RCTs, 50,812 participants, 28 single drugs, and 36 drug combinations) suggest that 29 out of 36 drug combinations and 10 out of 28 single drugs showed a clinically important benefit (defined as the upper end of the 95% confidence interval (CI) below a risk ratio (RR) of 0.8) compared to placebo. Combinations of drugs were generally more effective than single drugs in preventing vomiting. However, single NK_1 receptor antagonists showed treatment effects similar to most of the drug combinations. High-certainty evidence suggests that the following single drugs reduce vomiting (ordered by decreasing efficacy): aprepitant (RR 0.26, 95% CI 0.18 to 0.38, high certainty, rank 3/28 of single drugs); ramosetron (RR 0.44, 95% CI 0.32 to 0.59, high certainty, rank 5/28); granisetron (RR 0.45, 95% CI 0.38 to 0.54, high certainty, rank 6/28); dexamethasone (RR 0.51, 95% CI 0.44 to 0.57, high certainty, rank 8/28); and ondansetron (RR 0.55, 95% CI 0.51 to 0.60, high certainty, rank 13/28). Moderate-certainty evidence suggests that the following single drugs probably reduce vomiting: fosaprepitant (RR 0.06, 95% CI 0.02 to 0.21, moderate certainty, rank 1/28) and droperidol (RR 0.61, 95% CI 0.54 to 0.69, moderate certainty, rank 20/28).

Recommended and high doses of granisetron, dexamethasone, ondansetron, and droperidol showed clinically important benefit, but low doses showed no clinically important benefit. Aprepitant was used mainly at high doses, ramosetron at recommended doses, and fosaprepitant at doses of 150 mg (with no dose recommendation available).

Frequency of SAEs

Twenty-eight RCTs were included in the NMA for SAEs (10,766 participants, 13 single drugs, and eight drug combinations). The certainty of evidence for SAEs when using one of the best and most reliable anti-vomiting drugs (aprepitant, ramosetron, granisetron, dexamethasone, ondansetron, and droperidol compared to placebo) ranged from very low to low. Droperidol (RR 0.88, 95% CI 0.08 to 9.71, low certainty, rank 6/13) may reduce SAEs. We are uncertain about the effects of aprepitant (RR 1.39, 95% CI 0.26 to 7.36, very low certainty, rank 11/13), ramosetron (RR 0.89, 95% CI 0.05 to 15.74, very low certainty, rank 7/13), granisetron (RR 1.21, 95% CI 0.11 to 13.15, very low certainty, rank 10/13), dexamethasone (RR 1.16, 95% CI 0.28 to 4.85, very low certainty, rank 9/13), and ondansetron (RR 1.62, 95% CI 0.32 to 8.10, very low certainty, rank 12/13). No studies reporting SAEs were available for fosaprepitant.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Frequency of any AE

Sixty-one RCTs were included in the NMA for any AE (19,423 participants, 15 single drugs, and 11 drug combinations). The certainty of evidence for any AE when using one of the best and most reliable anti-vomiting drugs (aprepitant, ramosetron, granisetron, dexamethasone, ondansetron, and droperidol compared to placebo) ranged from very low to moderate. Granisetron (RR 0.92, 95% CI 0.80 to 1.05, moderate certainty, rank 7/15) probably has no or little effect on any AE. Dexamethasone (RR 0.77, 95% CI 0.55 to 1.08, low certainty, rank 2/15) and droperidol (RR 0.89, 95% CI 0.81 to 0.98, low certainty, rank 6/15) may reduce any AE. Ondansetron (RR 0.95, 95% CI 0.88 to 1.01, low certainty, rank 9/15) may have little or no effect on any AE. We are uncertain about the effects of aprepitant (RR 0.87, 95% CI 0.78 to 0.97, very low certainty, rank 3/15) and ramosetron (RR 1.00, 95% CI 0.65 to 1.54, very low certainty, rank 11/15) on any AE. No studies reporting any AE were available for fosaprepitant.

Class-specific side effects

For class-specific side effects (headache, constipation, wound infection, extrapyramidal symptoms, sedation, arrhythmia, and QT prolongation) of relevant substances, the certainty of evidence for the best and most reliable anti-vomiting drugs mostly ranged from very low to low. Exceptions were that ondansetron probably increases headache (RR 1.16, 95% CI 1.06 to 1.28, moderate certainty, rank 18/23) and probably reduces sedation (RR 0.87, 95% CI 0.79 to 0.96, moderate certainty, rank 5/24) compared to placebo. The latter effect is limited to recommended and high doses of ondansetron. Droperidol probably reduces headache (RR 0.76, 95% CI 0.67 to 0.86, moderate certainty, rank 5/23) compared to placebo. We have high-certainty evidence that dexamethasone (RR 1.00, 95% CI 0.91 to 1.09, high certainty, rank 16/24) has no effect on sedation compared to placebo. No studies assessed substance class-specific side effects for fosaprepitant.

Direction and magnitude of network effect estimates together with level of evidence certainty are graphically summarized for all pre-defined GRADE-relevant outcomes and all drugs of direct interest compared to placebo in http://doi.org/10.5281/zenodo.4066353.

Authors' conclusions

We found high-certainty evidence that five single drugs (aprepitant, ramosetron, granisetron, dexamethasone, and ondansetron) reduce vomiting, and moderate-certainty evidence that two other single drugs (fosaprepitant and droperidol) probably reduce vomiting, compared to placebo. Four of the six substance classes (5-HT_3 receptor antagonists, D_2 receptor antagonists, NK_1 receptor antagonists, and corticosteroids) were thus represented by at least one drug with important benefit for prevention of vomiting. Combinations of drugs were generally more effective than the corresponding single drugs in preventing vomiting. NK_1 receptor antagonists were the most effective drug class and had comparable efficacy to most of the drug combinations. 5-HT_3 receptor antagonists were the best studied substance class. For most of the single drugs of direct interest, we found only very low to low certainty evidence for safety outcomes such as occurrence of SAEs, any AE, and substance class-specific side effects.

Recommended and high doses of granisetron, dexamethasone, ondansetron, and droperidol were more effective than low doses for prevention of vomiting. Dose dependency of side effects was rarely found due to the limited number of studies, except for the less sedating effect of recommended and high doses of ondansetron.

The results of the review are transferable mainly to patients at higher risk of nausea and vomiting (i.e. healthy women undergoing inhalational anaesthesia and receiving perioperative opioids). Overall study quality was limited, but certainty assessments of effect estimates consider this limitation. No further efficacy studies are needed as there is evidence of moderate to high certainty for seven single drugs with relevant benefit for prevention of vomiting. However, additional studies are needed to investigate potential side effects of these drugs and to examine higher-risk patient populations (e.g. individuals with diabetes and heart disease).

PLAIN LANGUAGE SUMMARY

Which medicines work best to prevent people from being sick (vomiting) after an operation?

Why are people sick after an operation?

Feeling sick (nausea) or being sick (vomiting) is a common unwanted effect of general anaesthesia—medicine that makes people unconscious and unresponsive so they don't move or feel pain during an operation.

Most unwanted effects of general anaesthesia, including feeling or being sick, happen immediately and stop after a few hours, although some people may continue to feel sick for up to a day. If people carry on feeling or being sick, they might have to stay in hospital longer than expected and may experience other unwanted effects or complications.

Women are more likely to be sick after an operation, as are people taking opioid painkillers, those who have had motion sickness, and those who have been sick after previous operations.

Medicines to prevent people from being sick

Medicines called antiemetics are given to prevent people from feeling or being sick. These medicines may be given before or during anaesthesia.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Antiemetic medicines are grouped into six main classes based on how they act. Combining medicines from different classes sometimes makes them work better.

Why we did this Cochrane Review

We wanted to find out which medicines work best to prevent people from being sick after an operation and cause the fewest unwanted effects. Some unwanted effects of antiemetic medicines include headache, constipation, movement disorders such as tremors, sleepiness, irregular heartbeat, and wound infection.

What did we do?

We searched for studies that looked at the use of antiemetic medicines in adults having general anaesthesia to prevent people from being sick afterwards.

We looked for randomized controlled studies, in which the treatments people received were decided at random. This type of study usually gives the most reliable evidence about the effects of a treatment.

Search date

We included evidence published up to November 2017; in April 2020, we found another 39 studies, which are not yet included in the analysis.

What we found

We found 585 studies in 97,516 people who were given antiemetic medicines before or during general anaesthesia. People included in the studies were more likely to be sick after anaesthesia, as 83% were women and 88% were taking opioid painkillers. Most studies were conducted in Asia, Europe, or North America.

These studies either measured how many people were sick in the first 24 hours after their operation or how many unwanted effects were reported, or both of these outcomes. Most studies compared medicines (given alone or in combination) with a dummy (placebo) treatment.

We compared all antiemetic medicines with each other using a mathematical method called network meta-analysis.

What were our main results and how reliable are these results?

Compared with placebo treatment, 10 out of 28 single medicines and 29 out of 36 combinations of medicines prevented people from being sick in the first 24 hours after their operation (282 studies). Combinations of antiemetic medicines generally worked better than single medicines given alone. However, aprepitant, casopitant, and fosaprepitant worked as well alone as most combinations of antiemetics. The single medicine that worked best in the ranking of all medicines was fosaprepitant, followed by casopitant, aprepitant, ramosetron, granisetron, dexamethasone, tropisetron, ondansetron, dolasetron, and droperidol.

We are confident that aprepitant, ramosetron, granisetron, dexamethasone, and ondansetron prevent people from being sick. We are moderately confident about how well fosaprepitant and droperidol work, but this finding may change when further evidence becomes available. We are uncertain about how well casopitant, tropisetron, and dolasetron work.

Not all studies looked at serious, life-threatening unwanted effects. We are uncertain how many of these effects were reported when taking an antiemetic medicine and whether serious, life-threatening unwanted effects occur at a similar rate or are reduced compared to placebo (28 studies).

Of the best medicines with most reliable evidence for preventing being sick, granisetron and ondansetron probably made little to no difference in the occurrence of unwanted effects compared to placebo, whereas dexamethasone and droperidol may cause fewer unwanted effects than placebo. We are uncertain about unwanted effects with aprepitant and ramosetron (61 studies). We found no studies looking at unwanted effects for fosaprepitant.

We are less confident about unwanted effects of other antiemetic medicines because we found little reliable evidence about this. Our results for unwanted effects are likely to change when further evidence is available.

Conclusions

For people at higher risk, we found that some antiemetic medicines work well to prevent them from being sick after general anaesthesia. The best antiemetic medicines with reliable evidence were aprepitant, ramosetron, granisetron, dexamethasone, and ondansetron, followed by fosaprepitant and droperidol.

However, we did not find enough reliable evidence about potential unwanted effects to rank these medicines reliably according to how well they are tolerated.

SUMMARY OF FINDINGS

Summary of findings 1. Primary summary of findings

Primary summary of findings'

Estimates of effects and certainty of the evidence of antiemetic drugs for prevention of postoperative nausea and vomiting in adults after general anaesthesia

Patient or population: adults undergoing any type of surgery under general anaesthesia

Interventions: antiemetic drugs (single drugs and drug combinations)*

Comparator (reference): placebo (or no treatment)

Outcomes: all primary outcomes and drug class-specific adverse effects**

Setting: inpatient and outpatient

Outcomes	Effects and confidence in the estimate of effects (network meta-analysis)

NMA-SoF table definitions:

- Network estimates are reported as risk ratio (RR) with confidence interval.
- Anticipated absolute effects compare two risks by calculating the difference between risks of the intervention group and the control group.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

- Certainty of evidence (confidence) is reported for network estimates only.
- Ranking of treatments includes all single drugs and combinations of drugs and is based on the P score (a value on a continuous 0 to 1 scale), which measures the extent of certainty that a treatment is better than another treatment, averaged over all competing treatments. Larger P scores indicate better treatments. In addition, the rank of the treatment out of all single drugs is indicated.
- Information is given on the numbers of participants and studies included in the direct comparison and the contribution of indirect evidence (indirect evidence proportion).

* Selection criteria for presentation of interventions in this primary 'Summary of findings table': single antiemetic drugs of direct interest with important beneficial effect and with high or moderate certainty of evidence for the primary outcome (vomiting) were selected for presentation. These were aprepitant, ramosetron, granisetron, dexamethasone, ondansetron, fosaprepitant, and droperidol.

** Relevant adverse effects were selected according to the substance class: NK1 receptor antagonists (aprepitant, fosaprepitant): headache; 5-HT3 receptor antagonists (ramosetron, granisetron, ondansetron): headache, constipation; corticosteroids (dexamethasone): wound infection; D2 receptor antagonists (droperidol): extrapyramidal symptoms, sedation, arrhythmia, QT prolongation

GRADE Working Group grades of evidence (certainty of evidence).

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate. the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited. The true effect may be substantially different from the estimate of effect.

Very low certainty: we have very little confidence in the effect estimate. The true effect is likely to be substantially different from the estimate of effect.

Explanatory footnotes to baseline risks (assumed control risks):

[a] Baseline risk (assumed control risk) for vomiting within 24 hours was obtained from the consensus guideline on postoperative nausea and vomiting (Gan-2014). The general incidence of vomiting after surgery is about 30%.

[b] The baseline risk is based on the total events of all placebo groups included in the relevant outcome of the current network meta-analysis (mean control group risk across studies).

Explanatory footnotes to the ratings of the confidence in the network estimates:

[1] Evidence only for recommended and high doses because low doses showed no clinically important effect.

[2] Serious concerns for publication bias and heterogeneity. Publication bias and heterogeneity are overlapping domains for which we downgraded only once.

[3] Serious concerns for study limitations and incoherence, and very serious concerns for imprecision.

[4] Very serious concerns for study limitations and imprecision.

[5] Serious concerns for study limitations and very serious concerns for imprecision.

[6] Very serious concerns for imprecision.

[7] Very serious concerns for imprecision and serious concerns for incoherence.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

[8] Very serious concerns for study limitations.

[9] Poorly connected to the network. Only direct evidence is available.

Summary of findings 2. Summary of findings (vomiting within 24 hours postoperatively)

BENEFIT

Patient or population: adults undergoing any type of surgery under general anaesthesia

Interventions: antiemetic drugs (monoprophylaxis and combination prophylaxis)*

Comparator (reference): placebo (or no treatment)

Outcome: vomiting (or dry retching) within 24 hours postoperatively

Setting: inpatient and outpatient

NMA-SoF table definitions:

* Certainty of evidence was only assessed for single antiemetic drugs of direct interest.

** Geometry of the network is presented in Figure 12 (netgraph).

*** Network estimates are reported as risk ratio (RR) with confidence interval (CI).

**** Anticipated absolute effects. The anticipated absolute effect compares two risks by calculating the difference between risk of the intervention group and risk of the control group.

***** Ranking of treatments includes all single drugs and combinations of drugs and is based on the P score (a value on a continuous 0 to 1 scale), which measures the extent of certainty that a treatment is better than another treatment, averaged over all competing treatments (Supplementary Files-3-any AE). Larger P scores indicate better treatments. In addition, the rank of the treatment out of all single drugs is indicated.

GRADE working group grades of evidence (or certainty of the evidence).

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate. The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited. The true effect may be substantially different from the estimate of effect.

Very low certainty: we have very little confidence in the effect estimate. The true effect is likely to be substantially different from the estimate of effect.

Explanatory footnotes:

[1] Baseline risks (assumed control risk) are based on the total events of all placebo groups included in the outcome any AE. The general incidence of any AE after surgery with placebo is about 37.68%.

[2] Very serious concern for study limitations and serious concerns for imprecision and heterogeneity. Imprecision and heterogeneity are overlapping domains for which we downgraded only once.

[3] Poorly connected to the network. Only direct evidence available.

[4] Serious concerns for study limitations and very serious concerns for imprecision.

[5] Very serious concerns for imprecision.

[6] Poorly connected to the network. Aprepitant was directly compared only to ondansetron.

[7] Poorly connected to the network. Dimenhydrinate was directly compared only to ondansetron.

[8] Very serious concerns for study limitations.

Summary of findings 5. Summary of findings (headache)

NMA-SoF table definitions:

* Certainty of evidence was assessed only for single antiemetic drugs of direct interest.

** Geometry of the network is presented in Figure 16 (netgraph).

*** Network estimates are reported as risk ratio (RR) with confidence interval (CI).

**** Anticipated absolute effects. The anticipated absolute effect compares two risks by calculating the difference between risk of the intervention group and risk of the control group.

***** Ranking of treatments includes all single drugs and combinations of drugs and is based on the P score (a value on a continuous 0 to 1 scale), which measures the extent of certainty that a treatment is better than another treatment, averaged over all competing treatments (Supplementary Files-5-sedation). Larger P scores indicate better treatments. In addition, the rank of the treatment out of all single drugs is indicated.

GRADE working group grades of evidence (or certainty of the evidence).

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate. The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited. The true effect may be substantially different from the estimate of effect.

Very low certainty: we have very little confidence in the effect estimate. The true effect is likely to be substantially different from the estimate of effect.

Explanatory footnotes:

[1] Baseline risks (assumed control risk) are based on the total events of all placebo groups included in the outcome sedation. The general incidence of sedation after surgery with placebo is about 13%.

[2] Very serious concerns for imprecision.

[3] Serious concerns for study limitations and very serious concerns for imprecision.

[4] Evidence only for recommended and high doses.

[5] Poorly connected to the network. Only direct evidence available.

[6] Very serious concerns for study limitations.

NMA-SoF table definitions:

* Certainty of evidence was assessed only for single antiemetic drugs of direct interest.

** Geometry of the network is presented in Figure 22 (netgraph).

*** Network estimates are reported as risk ratio (RR) with confidence interval (CI).

**** Anticipated absolute effects. The anticipated absolute effect compares two risks by calculating the difference between risk of the intervention group and risk of the control group.

***** Ranking of treatments includes all single drugs and combinations of drugs and is based on the P score (a value on a continuous 0 to 1 scale), which measures the extent of certainty that a treatment is better than another treatment, averaged over all competing treatments (Supplementary Files-8-wound infection). Larger P scores indicate better treatments. In addition, the rank of the treatment out of all single drugs is indicated.

GRADE working group grades of evidence (or certainty of the evidence).

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate. The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited. The true effect may be substantially different from the estimate of effect.

Very low certainty: we have very little confidence in the effect estimate. The true effect is likely to be substantially different from the estimate of effect.

Explanatory footnotes:

[1] Baseline risks (assumed control risk) are based on the total events of all placebo groups included in the outcome wound infection. The general incidence of wound infection after surgery with placebo is about 0.44%.

[2] Very serious concerns for imprecision and serious concerns for incoherence.

[3] Serious concerns for study limitations and very serious concerns for imprecision.

[4] Poorly connected to the network. Only direct evidence available.

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate. The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited. The true effect may be substantially different from the estimate of effect.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Very low certainty: we have very little confidence in the effect estimate. The true effect is likely to be substantially different from the estimate of effect.

BACKGROUND

Description of the condition

Postoperative nausea and vomiting (PONV) is one of the major and most frequently observed problems anaesthetists and patients have to face after surgical procedures. In the majority of cases, PONV occurs during the first 24 hours postoperatively with a peak in the immediate postoperative hours (Apfel 2002). About 30% of all patients undergoing anaesthesia using volatile anaesthetics without prior prophylaxis are affected by PONV after surgery (Apfel 1999). In 1998, Apfel and colleagues developed a simplified score that helps to predict individual risk for the occurrence of PONV in adults. The four risk factors included are female gender, non-smoker status, history of PONV or motion sickness, and expected postoperative opioid use (Doleman 2018). Apfel suggests that the likelihood of PONV ranges from 10% (no risk factors present) to 79% (all four risk factors present) (Apfel 1999). The incidence of PONV varies with a number of other factors,including hydration status (Jewer 2019), type of anaesthetic (intravenous versus inhalational (Miller 2018)) and possibly depth of anaesthesia (Lewis 2019). The use of opioids can be avoided or minimised through the use of regional anaesthetic techniques (Weinstein 2018) or systemic, non-opioid analgesics such as lidocaine (Weibel 2018).

Rarely described but serious consequences of PONV that are usually secondary to vomiting include aspiration pneumonia, Boerhaave's syndrome, and severe subcutaneous emphysema (Attalah 2004; Baric 2000; Kranke 2011; Reddy 2008; Schumann 1999). However, PONV is itself an unpleasant and uncomfortable feeling and a burdensome side effect for patients receiving anaesthesia (Kranke 2011). It is subjectively rated to be as serious as postoperative pain and has an important influence on the quality of recovery (Hocking 2013; Kranke 2011). Moreover, PONV can lead to a prolonged or unexpected hospital stay, or even to re-admission. It also interferes with early postoperative recovery (Kranke 2011).

Description of the intervention

A large variety of antiemetic drugs—grouped into six different drug classes—are available for prevention of PONV (Gan 2007a; Gan 2014; Horn 2014; Wiesmann 2015): 5-HT_3 receptor antagonists (e.g. ondansetron, dolasetron, granisetron, tropisetron, ramosetron, palonosetron); D_2 receptor antagonists (e.g. droperidol, haloperidol, metoclopramide, perphenazine, amisulpride, alizapride, chlorpromazine, domperidone, prochlorperazine, sulpiride, trimethobenzamide); NK_1 receptor antagonists (e.g. aprepitant, casopitant, rolapitant, fosaprepitant, CP-122,721, vestipitant); corticosteroids (e.g. dexamethasone, methylprednisolone, betamethasone); antihistamines (e.g. dimenhydrinate, meclizine, promethazine, cyclizine); and anticholinergics (i.e. scopolamine).

The six different substance classes are characterized by varying adverse effects: 5-HT_3 receptor antagonists (e.g. headache, constipation), D_2 receptor antagonists (e.g. extrapyramidal symptoms, sedation, arrhythmia, QT prolongation), corticosteroids (e.g. hyperglycaemia, immunosuppression, wound healing deficits), antihistamines (e.g. drowsiness, xerostomia, urinary tract difficulties), and anticholinergics (e.g. dry mouth, visual disturbances) (Gan 2014; Horn 2014; Wiesmann 2015). Currently limited evidence is available on adverse effects arising from NK_1 receptor antagonists. However, increased dizziness or headache was described by individual studies (Diemunsch 2009).

Drugs with different mechanisms of action should be used in combination to optimize efficacy (Gan 2007b). For example, the 5-HT_3 antagonists, which have better anti-vomiting than anti-nausea efficacy (although associated with headache), can be used in combination with droperidol, which has greater anti-nausea efficacy and a protective effect against headache (Gan 2007b).

In addition to drugs with direct antiemetic action, several other strategies for PONV prophylaxis are available such as use of drugs with indirect opioid-sparing effects (e.g. gabapentin; Grant 2016), or strategies such as reducing the emetic potency of the anaesthesia itself (e.g. by using propofol; Apfel 2004), or non-pharmacologic prophylaxis strategies (e.g. stimulation of the wrist acupuncture point PC6; Lee 2015). These strategies are not within the focus of the current review.

Gan 2014 in its 'Consensus guidelines for the management of postoperative nausea and vomiting' provides information about current options for prevention and treatment of PONV including both pharmacologic and non-pharmacologic regimens comprising the most commonly used antiemetic drugs, doses, and timing of application. With adequate prophylaxis, one antiemetic agent can reduce the likelihood (relative reduction) of PONV by 25% (Gan 2014). This evidence-based guideline currently recommends one to two interventions for PONV prophylaxis for patients at moderate risk (Gan 2014).

It is important to provide adequate prophylaxis with regard to the type and time of application. Intravenous or parenteral application of antiemetics in accordance with their pharmacokinetic profile may be appropriate for mitigating the risk of the varying duration of surgery and the need for a reasonably effective drug level at the 'time of risk' in the postoperative setting. A large majority of antiemetic drugs are usually administered by a slow intravenous push or as an infusion administered over a short time. Although some 'alternative' therapies are available (e.g. aromatherapy (Hines 2018)), this review does not include such substances.

How the intervention might work

Five of the six substance classes with direct antiemetic effects differ mostly in their antagonistic action against different emetogenic substances at specific receptors, for example, in the area postrema or on the free nerve endings of the vagus nerve (Gan 2007a; Gan 2014; Horn 2014; Wiesmann 2015).

- 5-HT_3 receptor antagonists: high levels of the neurotransmitter serotonin (5-hydroxytryptamine, 5-HT) induce nausea and vomiting by activating specific receptors in the gut and central nervous system. Drugs belonging to this substance class inhibit serotonin receptors centrally and peripherally.
- D_2 receptor antagonists: dopamine antagonists work as antiemetics in small dosages by blocking central dopamine receptors.
- NK_1 receptor antagonists: the neurotransmitter substance P binds to the neurokinin 1-receptor in the area postrema and thereby induces nausea and vomiting. NK_1 receptor antagonists block these receptors and inhibit this pathway.
- Antihistamines (histamine 1 receptor antagonists): the tissue hormone histamine induces nausea and vomiting

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

by activating central H_1-receptors. Antihistamines for PONV prevention predominantly block these receptors but also have anticholinergic effects.

- Anticholinergics: anticholinergic agents have a parasympatholytic effect by inhibiting binding between the neurotransmitter acetylcholine and the muscarinic receptor centrally.

A sixth group of antiemetics with direct antiemetic effects consists of corticosteroids. It is not known with any certainty how corticosteroids exert their antiemetic effects. Some theories assume that the anti-inflammatory impact and the decrease in arachidonic acid release reduce the occurrence of PONV.

Why it is important to do this review

Preventing PONV is important for the well-being of patients and is a major factor influencing patients' satisfaction with anaesthesia. It is therefore important for patients to be provided with sufficient antiemetic prophylaxis. PONV is also a major contributor to direct and indirect healthcare costs (Eberhart 2014; Hirsch 1994). Amongst others, these include costs for prolonged stays in recovery rooms and costs of extra nursing time (Hirsch 1994; Smith 2012). In times when healthcare resources are scarce and the healthcare workforce is decreasing, the correct prophylaxis offers an advantage. Many antiemetics have proven efficacy for clinical use. Unfortunately, the use of prophylactic antiemetics for patients at risk is not part of the daily routine of all anaesthetists due to inadequate implementation of the risk-adapted approach in some clinical departments (Franck 2010). Moreover, risk–benefit issues remain a topic of debate in the anaesthesia community, and the fear of possible adverse effects (Weibel 2018) may be another reason for restraint (Kranke 2011).

Many studies have investigated not only monotherapies but also combinations of antiemetics to reduce the likelihood of developing PONV. Trials examining different doses or dose ranges of one or more drugs administered in various ways (intravenous, intramuscular, oral, or transdermal) create a wide spectrum of information that is difficult to assess by simple direct comparisons.

In 2006, Carlisle and Stevenson performed a systematic review that assessed all available drugs with antiemetic action for preventing PONV in adults and children in terms of efficacy and side effects. This review included more than 700 studies with over 100,000 participants (Carlisle 2006a). All trials reporting PONV as an outcome and comparing a drug with placebo, no treatment, or another drug, or comparing different dosing or timing of administration, were included. This review contained a large number of direct comparisons, as no restrictions regarding study population or type of intervention were defined.

Tricco and colleagues published a systematic review with network meta-analysis (NMA) of the efficacy and safety of serotonin receptor antagonists compared to each other, compared to placebo, and in combination with other antiemetic agents for PONV prevention (Tricco 2015a; Tricco 2015b). However, these review authors examined no other substance classes.

Despite the continuing flow of clinical trials on PONV prophylaxis, there is still no current overview of all relevant substance classes. There is a shortage of direct comparisons of frequently used antiemetics, and a clinically useful ranking of all antiemetic drugs with respect to both efficacy and safety is lacking. The Carlisle review of PONV needs to be updated (Carlisle 2006a). However, the original review was withdrawn in 2017, in part because several studies that had been included were retracted since publication (Carlisle 2017). Another reason for withdrawal was that the literature is now so large and complex that a very large series of direct comparisons—as performed in the Carlisle review of PONV—would create an overwhelmingly burdensome task and would be very difficult to comprehend. Therefore, a new and more efficient approach was needed to allow readers to appreciate readily the best-quality evidence available. For the current review, we performed an NMA that allows comparison of antiemetic drugs in a direct and indirect manner (see Methods). The aim of this review is to generate a clinically useful ranking of antiemetic drugs (monotherapy and combination prophylaxis). This review also seeks to provide clear information for patients and physicians to guide clinical decisions that enhance treatment efficacy and reduce the occurrence of side effects. To enhance the feasibility, we made a pre hoc decision to focus on the six clinically relevant drug classes with direct antiemetic action currently used or under investigation. Drugs such as gabapentin, which exert an antiemetic effect in an indirect way via an opioid-sparing effect (Grant 2016), as well as non-pharmacologic interventions (Lee 2015), are not within the scope of this review. This systematic review is deliberately designed to address some of the questions raised by the current PONV guideline (Gan 2014), with the aim of providing an evidence-based basis for future updates to this guideline.

OBJECTIVES

- To compare the efficacy and safety of different prophylactic pharmacologic interventions (antiemetic drugs) against no treatment, against placebo, or against each other (as monotherapy or combination prophylaxis) for prevention of postoperative nausea and vomiting in adults undergoing any type of surgery under general anaesthesia
- To generate a clinically useful ranking of antiemetic drugs (monotherapy and combination prophylaxis) based on efficacy and safety
- To identify the best dose or dose range of antiemetic drugs in terms of efficacy and safety

METHODS

Criteria for considering studies for this review

Types of studies

In this review, we included randomized controlled trials (RCTs) that compare one or more antiemetics for prevention of PONV against no treatment, placebo, or another antiemetic drug. We excluded quasi-randomized trials (i.e. trials in which treatment allocation is achieved by date of birth, alternation, or similar predictable methods), cluster-randomized trials, and cross-over studies.

We included trials in which allocation to treatment may not have been adequately concealed, but we considered trial methodological quality in data analyses and interpretation.

We did not restrict inclusion of studies based on language of publication.

Retracted studies and studies authored by Fujii and colleagues were not included in the review (Kranke 2000; Tramer 2013).

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Eligible studies must have been reported as full-text journal publications or comprehensive study reports. Because we expected to identify more than 1000 full-text studies, we excluded studies published in abstract form only to reduce the workload and to enhance the feasibility of completing the review in a reasonable time frame.

Types of participants

We included only trials that analysed adult participants (i.e. the majority of participants over 18 years of age) undergoing any type of surgery under general anaesthesia. We did not include studies using regional or sedative anaesthetic techniques.

Types of interventions

We included studies that compared any pharmacologic intervention(s) with antiemetic action belonging to one of the following drug classes versus each other or versus no treatment, or versus placebo.

- 5-HT_3 receptor antagonists.
- D_2 receptor antagonists.
- NK_1 receptor antagonists.
- Corticosteroids.
- Antihistamines (histamine 1 receptor antagonists).
- Anticholinergics.

For future updates, we may include emerging drugs from other drug classes if it has been demonstrated that they exert a direct antiemetic action.

We also included trials that analysed combinations of antiemetic drugs, whereby each combination represents a separate intervention of interest and therefore a separate node in the NMA (splitting). In the run-up to the NMA, we assessed the geometry of the network (all interventions (monotherapy and combination prophylaxis) versus monoprophylaxis alone). We aimed to examine all possible combination prophylaxis treatments in cases where the geometry of the network allowed this holistic approach. All networks in the current review were well connected.

Different doses of drugs were combined into one node (lumping). Dose effects were analysed in subgroup analyses, especially in cases of heterogeneity or inconsistency.

Not all eligible interventions from the various drug classes were of direct (primary) interest. All drugs of direct interest for the review with highest clinical relevance are listed in the section "Interventions of direct interest". Eligible interventions not of direct interest were included in the network to increase the amount of available (indirect) information in the analysis (see "Inclusion of additional interventions to supplement the analysis") (Ades 2013; Protocol Template 2014).

For inclusion, the antiemetic drug(s) had to have been administered before the onset of PONV. These drug(s) could have been given preoperatively, at induction of anaesthesia, or during anaesthesia.

Participants in all treatment arms within a study must have been subject to the same anaesthesia regimen with comparable dosing because the anaesthesia management itself may have an influence on the incidence of PONV. For studies that reported results separately for varying baseline anaesthesia regimens, the different regimens were not combined but were considered as sub-studies.

We assumed that, in principle, any participant meeting the inclusion criteria could be selected at random for one of the eligible interventions.

Interventions of direct interest

Antiemetic drugs of direct interest in the current review include those recommended in the "Consensus guidelines for the management of postoperative nausea and vomiting" (Gan 2014), as well as promising and emerging substances such as fosaprepitant and amisulpride. We planned to consider any other drug as an 'intervention of direct interest' if it was investigated in more than two studies with more than 400 participants and was published in the last five years before the search date (2017). In the current review, none of the antiemetics not currently listed in the "Interventions of direct interest" section fulfilled these criteria. Therefore, all other drugs were analysed as 'additional interventions to supplement the analysis'. The current review includes the following 'interventions of direct interest'.

- 5-HT_3 receptor antagonists: dolasetron (dola), granisetron (gran), ondansetron (onda), palonosetron (palo), ramosetron (ramo), and tropisetron (trop).
- D_2 receptor antagonists: amisulpride (amis), droperidol (drop), haloperidol (halo), metoclopramide (meto), and perphenazine (perp).
- NK_1 receptor antagonists: aprepitant (apre), casopitant (caso), fosaprepitant (fosa), and rolapitant (rola).
- Corticosteroids: dexamethasone (dexa) and methylprednisolone (meth).
- Antihistamines (histamine 1 receptor antagonists): dimenhydrinate (dime), meclizine (mecl), and promethazine (prom).
- Anticholinergics: scopolamine (scop).

We restricted all exploratory analyses and assessment of the certainty of evidence to the 'interventions of direct interest' and reported the findings in detail in this review.

Additional interventions to supplement the analysis

Eligible interventions not of direct interest were included in the network to increase the amount of available information included in the analysis. The following antiemetic drugs were considered as 'additional interventions to supplement the analysis'.

- 5-HT_3 receptor antagonists: azasetron (aza).
- D_2 receptor antagonists: alizapride (aliz), buspirone (busp), chlorpromazine (chlo), domperidone (domp), levomepromazine (levo), olanzapine (olan), prochlorperazine (proc), sulpiride (sulp), thiethylperazine (thie), and trimethobenzamide (trim).
- NK_1 receptor antagonists: CP-122,721 (cp12) and vestipitant (vest).
- Corticosteroids: betamethasone (beta) and prednisolone (pred).
- Antihistamines (histamine 1 receptor antagonists): benzquinamide (benz), cetrizine (cetr), cyclizine (cycl), dixyrazine (dixy), and doxylamine/diclectin (doxy).

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

- Anticholinergics: diphenidol (diph), oxybutynin (oxyb), and penehyclidine (pene).

Types of outcome measures

Studies must have reported at least one of the following primary or secondary outcomes to be fully eligible for and to be included in the review. Reporting of outcomes of interest was an essential eligibility criterion to enhance the feasibility of the review workload.

Primary outcomes

We estimated the relative effects of competing interventions according to the following primary outcomes.

- Vomiting (or dry retching) within 24 hours: number of participants with events within 0 to 24 hours (± 6 hours) postoperatively.
- Serious adverse events (SAEs): number of participants with at least one SAE (as defined in the study) in the observation period (up to seven days).
- Any adverse event (AE): number of participants with at least one AE (as defined in the study) in the observation period (up to seven days).

Secondary outcomes

We estimated the relative effects of competing interventions according to the following secondary outcomes.

Substance class-specific side effects

- Headache: number of participants with headache in the observation period (up to seven days)
- Sedation/drowsiness: number of participants with sedation/drowsiness in the observation period (up to seven days)
- Extrapyramidal symptoms: number of participants with extrapyramidal symptoms (e.g. dystonia, dyskinesia, akathisia, bradykinesia, tremor) in the observation period (up to seven days)
- Constipation: number of participants with constipation in the observation period (up to seven days)
- Postoperative wound infection: number of participants with postoperative wound infection in the observation period (up to seven days)
- Arrhythmia: number of participants with an arrhythmia (as defined by triallists) in the observation period (up to seven days)
- Visual disturbances: number of participants with visual disturbances (e.g. blurred vision) in the observation period (up to seven days)
- QT prolongation: number of participants with a QT prolongation (as defined by triallists) in the observation period (up to seven days)

Other secondary outcomes

- Mortality: number of participants who have died in the observation period (up to seven days)
- Early postoperative vomiting (or dry retching): number of participants with events within an observation period starting immediately after anaesthesia and ending two to six hours later (or defined as occurring in the postanaesthesia care unit (PACU))
- Late postoperative vomiting (or dry retching): number of participants with events within an observation period within the range of two to 24 hours postoperatively. If studies have recorded the outcome during different periods of the two to 24 hour postoperative period but have not reported the risk for the complete observation period (two to 24 hours), we reported the risk of the outcome once for each study using the risk for the period in which the outcome was most common (all groups combined)
- Nausea within 24 hours postoperatively (0 to 24 hours ± 6 hours): studies that have reported the combined endpoint PONV only (and not nausea separately) were considered as nausea. We did not include in the analysis continuous data on nausea (such as grades of nausea measured on appropriate scales)
- Complete response: number of participants without vomiting, nausea, or any need for rescue treatment within 24 hours postoperatively

Search methods for identification of studies

We searched for all kinds of comparisons involving the research question.

Electronic searches

We identified RCTs through literature searching designed to identify relevant trials, as outlined in Chapter 4 of the *Cochrane Handbook for Systematic Reviews of Interventions* (Lefebvre 2019). We did not apply language restrictions.

We searched the following databases for relevant trials (first search 2017 November 6, update search 2020 April 23).

- Cochrane Central Register of Controlled Trials (CENTRAL; 2020, Issue 4).
- MEDLINE (Ovid SP, 1946 to 2020 April 20).
- Embase (Ovid SP, 1974 to 2020 April 20).
- Cumulative Index to Nursing and Allied Health Literature (CINAHL) via EBSCO host (1982 to 2020 April 20).

We developed a draft search strategy for MEDLINE, which we used as the basis for the search strategies applied in the other databases listed. These search strategies can be found in Appendix 1.
We scanned the following trials registries for study reports and protocols, and for ongoing and unpublished trials.

- ClinicalTrials.gov (2 November 2017).
- World Health Organization International Clinical Trials Registry Platform (WHO ICTRP) (3 November 2017).

In the updated search in 2020, the study registries were not searched. Records of the ClinicalTrial.gov and WHO ICTRP databases were systematically added to CENTRAL, starting in August 2017 and April 2019. These records are therefore covered in the updated CENTRAL search. The WHO ICTRP trial register was closed at the date of the update search because of COVID-19. Therefore, the WHO ICTRP search is currently not complete.

All included trials have been checked against the Retraction Watch database (November 2018).

Searching other resources

We scanned the reference lists of relevant systematic reviews for additional trials (Carlisle 2006a; De Oliveira 2013; Liu 2015; Tricco 2015a; Tricco 2015b).

Data collection and analysis

Selection of studies

We used Covidence, a web-based software platform (Covidence), for the process of study selection. All records identified by the search strategy described above were imported into Covidence. The following review authors participated in the screening of records: SW, DM, MR, HH, AH, PKr, IB, DR, LE, MS, and TS. In each case, two of them independently screened the title and abstract of an individual record for eligibility using a pre-defined eligibility checklist (Appendix 2). For all potentially relevant records, we retrieved the full texts before making the final decision about which studies satisfied the inclusion criteria. When necessary, we contacted trial authors for missing information (18 requests sent to authors; none answered). All full texts were reviewed by two independent review authors. We resolved any discrepancies in judgement by discussion with a third review author (SW, PKr).

Data extraction and management

Two independent review authors extracted the data using a pre-defined data extraction form in the Covidence environment (Appendix 3; Covidence). Extracted data included data on outcomes and potential effect modifiers, along with other data. The following review authors participated in data extraction: SW, DM, MR, HH, AH, PKr, IB, DR, LE, and MS. A third review author (SW) checked all data extraction forms and resolved any discrepancies. When necessary, we contacted trial authors to request missing information (17 requests sent to authors; seven provided data). We exported data from Covidence into Review Manager software and Excel spreadsheets, and we checked them for accuracy (SW, OJ) (Review Manager 2014).

Basic study characteristics

We extracted from each included study data on the following additional information.

- Identification (year of publication; journal; first author (with contact information); location of study conduct; number of centres; duration of study; and trial registry number).
- Methods (study design and groups).
- Population details (inclusion and exclusion criteria with group differences; and participant flow (number of participants assessed for eligibility, number randomized, number that received treatment, and number analysed)).
- Prognostic variables (population and baseline characteristics, risk factors for PONV: gender; smoking status; history of PONV/motion sickness; type of surgery; type of anaesthesia; duration of anaesthesia; and use of perioperative opioids).

Outcome data

We extracted from each included study all data relevant to the primary and secondary outcomes listed in the section Types of outcome measures.

We extracted the following characteristics associated with monitoring and reporting of (severe) adverse events in each primary study.

- Type of monitoring for SAEs/AEs (active or passive).
- Types of AEs (defined AEs or any AEs).
- Use of an accepted international classification for SAEs (e.g. according to the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) guidelines).
- Number of SAEs reported (yes or no).

Data on potential effect modifiers

From each included study, we extracted data on the following potential effect modifiers.

- Intervention (dose; time point of administration (early versus late (after incision)); and route of administration).
- Risk of bias (sequence generation; blinding of participant, personnel, and outcome assessors; and incomplete outcome data).
- Funding source (sponsorship source and involvement).

Assessment of risk of bias in included studies

We assessed the risk of bias for each included study by using the Cochrane 'Risk of bias' assessment tool 1.0 (Higgins 2011). Standard items include random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessors, incomplete outcome data, selective reporting, and any other bias. We judged each item as being at 'low risk of bias', 'high risk of bias', or 'unclear risk of bias'. We included a 'Risk of bias' table as part of the Characteristics of included studies table and the 'Risk of bias summary'/'Risk of bias graph' figures, which detailed all of the judgements made for all studies included in the review.

We also assessed the characteristics associated with monitoring and reporting of severe and any adverse events in each primary study and reported this information in an additional table—"Assessment of adverse event monitoring"—along with a judgement on the risk of bias as described by Tramacere and colleagues (Tramacere 2015).

Two review authors independently performed study quality assessment using a pre-defined critical appraisal form in the Covidence environment (Appendix 4). We resolved any disagreements by discussion with a third review author (SW).

Random sequence generation

We considered sequence generation as adequate if it was generated by a random system (i.e. a computer, a random number table algorithm, or tossing of a coin). We considered sequence generation inadequate if a non-random system was used (i.e. names or dates). We excluded quasi-randomized trials. We assessed the study as having 'unclear risk of bias' if the only information on randomization was a statement that the study was randomized.

Allocation concealment

We considered concealment adequate if an acceptable method was used to ensure that group assignment was not revealed to patient recruiters, investigators, or participants before final allocation into the respective group. Acceptable methods included a central allocation system, sequentially numbered sealed opaque envelopes (SNOSEs), or an on-site locked computer. We considered concealment to be inadequate if it allowed patient recruiters, investigators, or participants to know the treatment allocation in advance. We assessed the study as having 'unclear risk of bias' if

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

the concealment procedure was not reported or was not sufficiently reported.

Blinding of participants and personnel outcome assessors

We considered blinding adequate if all participants and personnel (e.g. anaesthetists) were blinded to the intervention. We considered blinding inadequate if participants and personnel were not blinded to the intervention. We assessed the study as having 'unclear risk of bias' if study authors stated only that the study was blinded and if it remained unclear who was blinded.

Blinding of outcome assessors

We considered blinding adequate if all outcome assessors were blinded to the intervention. We considered blinding inadequate if outcome assessors were not blinded to the intervention. We assessed the study as having 'unclear risk of bias' if study authors stated only that the study was blinded and if it remained unclear who was blinded.

Incomplete outcome data

We considered the domain 'incomplete outcome data' as adequate if the number of dropouts was 15% or less and was balanced between arms, and if the reasons for dropout were reported and appeared to be unrelated to the studied outcomes. We considered outcome data as incomplete if the number of dropouts was greater than 15% or was significantly imbalanced between groups, or if the reasons for dropout were not reported or appeared to be related to outcomes of interest in the study. We assessed the study as having 'unclear risk of bias' if details on the number of dropouts and reasons for dropout were not sufficiently reported.

Selective outcome reporting

We assessed selective outcome reporting by comparing the type and order of outcomes (primary versus secondary) reported in the study protocol, along with the published outcomes. We considered outcome reporting as adequate if a prospectively registered study protocol was available, and if all primary and secondary outcomes were also reported in the published study as prespecified in the protocol. We judged selective outcome reporting as having 'high risk of bias' if the pre-defined primary outcomes in the registered protocol differed from those in the published study report. If no prospectively registered study protocol was available, we assessed selective outcome reporting as having 'unclear risk of bias'.

Other sources of bias

Other potential risks of bias included baseline imbalance in population characteristics and risk factors for PONV (prognostic variables) within studies that are strongly related to outcome measures and therefore may cause bias in the intervention effect estimate. An imbalance was defined as either a 20% difference between groups or $P < 0.05$ for a difference between two groups, if reported in the study. We assessed the study as having 'unclear risk of other bias' if details on baseline characteristics or risk factors for PONV were not sufficiently reported.

Overall risk of bias summary

We summarized the risk of bias for each study by referring to judgements for the most important domains 'sequence generation', 'blinding of participant, personnel, and outcome assessors', and 'incomplete outcome data'. We did not include in the overall risk of bias summary the domains 'allocation concealment' (for explanation, see Differences between protocol and review), 'selective outcome reporting', and 'other sources of bias'. The review included studies published over a time span of 50 years, and judgements on the domains 'selective outcome reporting' and 'other sources of bias' strongly depend on the year the study was conducted. Older studies (before 2000) were not registered in trial registries, and risk factors for PONV were not specified at older dates. We performed sensitivity analyses with information from the domain 'other sources of bias'.

We classified each study as having 'low risk of overall bias' when we judged all relevant domains as having 'low risk of bias'. If we judged at least one domain as having 'high risk of bias' or all domains as having 'unclear risk of bias', we classified overall risk of bias for the study as 'high risk of overall bias'. In the remaining cases, we classified the study as having 'unclear risk of overall bias'. We used information from the 'overall risk of bias summary' when performing sensitivity analyses.

Assessment of adverse event monitoring

The way of monitoring adverse events may introduce bias to the relevant adverse outcomes. Therefore, we assessed the risk of bias associated with monitoring for adverse events. We evaluated the methods of monitoring for adverse events in each primary study on the basis of the following questions as described by Tramacere and colleagues with some modifications (Tramacere 2015).

- Any AE.
  - Did the authors pro-actively monitor for any AE?
  - Did the authors simply provide spontaneous reporting (passively) of AEs by participants?
  - Did the authors report all relevant (class-specific) AEs?
- SAEs.
  - Did the authors define SAEs according to an accepted international classification?

We did not include this information in the 'Risk of bias' table. We reported this information in an additional table 'Monitoring and reporting of any (severe) adverse events', along with a judgement of the risk of bias (Tramacere 2015).

We used information from the assessment of adverse event monitoring to test the robustness of effect estimates for the primary outcomes 'SAEs' and 'any AE' by sensitivity analyses (exclusion of 'high and unclear risk of bias' studies for adverse event monitoring).

Review of network geometry

We graphically evaluated the geometry of the whole network including interventions of direct interest (monotherapy and combination prophylaxis) and any other intervention in which we were not directly interested (see 'Additional interventions to supplement the analysis') using the function netgraph of the R package netmeta (Rücker 2016; netmeta). We used the information from the network geometry to determine whether a network meta-analysis was feasible for all interventions or only for sub-networks (e.g. monoprophylaxis). The network is laid out in the plane as a circle, where the nodes in the graph layout correspond to the treatments and edges display the observed (direct) treatment comparisons. The thickness of the edges is proportionate to the number of included studies comparing two treatments.

Measures of treatment effect

Relative treatment effects

We estimated the pair-wise relative treatment effects of competing interventions using the risk ratio (RR) with 95% confidence intervals (95% CIs) for each outcome.

Results from network meta-analyses were presented as summary relative effects (RR) for each possible pair of treatments.

Relative treatment ranking

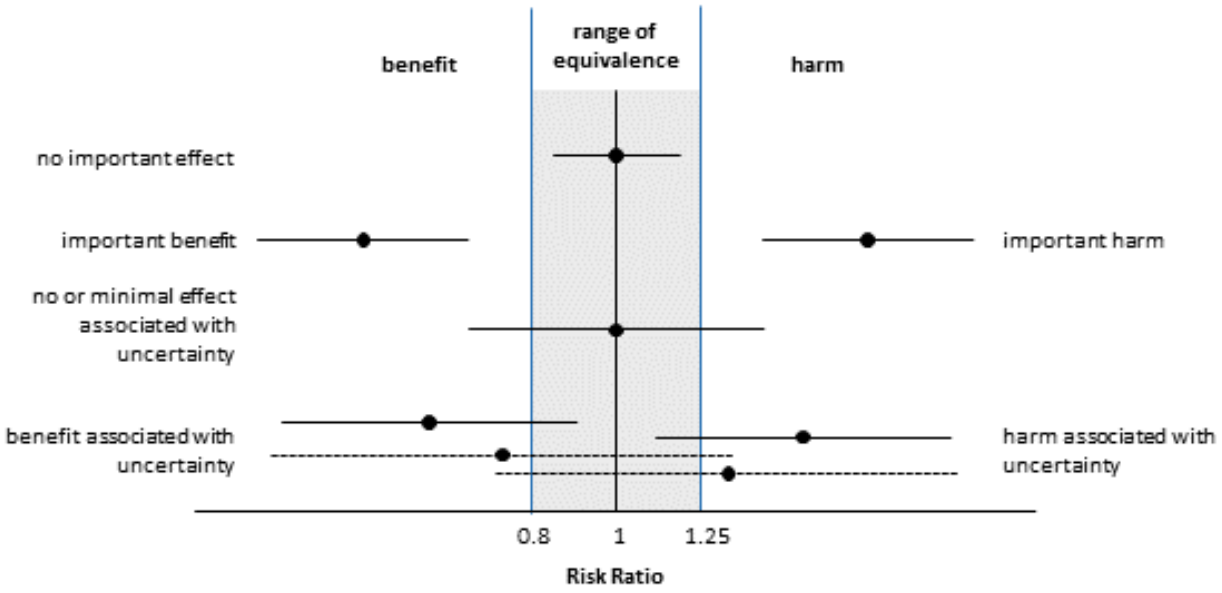
We ranked competing treatments by P scores (Rücker 2015), using the function netrank of the R package netmeta (netmeta). We used this method to measure the extent of certainty that a treatment is better than another treatment, averaged over all competing treatments (Rücker 2015). P scores should not be confused with P values. P scores are the frequentist analogue and are numerically similar to Bayesian surface under the cumulative ranking curve (SUCRA) values (Rücker 2015). P scores are ranking numbers between 0 and 1 that are derived from the P values of all pair-wise comparisons. Treatments are ranked from best to worst according to decreasing P scores for all outcomes with the exception of complete response (increasing P scores).

We looked at comparative efficacies between antiemetic drugs and expressed this finding using placebo as the reference intervention and presented the results in forest plots. We ranked treatment effects in forest plots according to P scores in decreasing order (the most effective intervention is presented at the top).

Size of effects

We used clinically relevant size of effects rather than statistical significance to describe network meta-analysis estimates (Nikolakopoulou 2019 Wasserstein 2019). For efficacy outcomes such as prevention of vomiting or nausea, we defined the clinically important size of benefit as RR of 0.80 and the reciprocal as clinically important harm (RR 1.25). Effects lower than 0.80 and larger than 1.25 were considered to be clinically important. The range between 0.8 and 1.25 was termed the 'range of equivalence', which included unimportant treatment effects (Nikolakopoulou 2019). The relative position of the point estimates indicated the direction of the effect as 'benefit', 'no or minimal effect', or 'harm' (Figure 1). The extent of the 95% CI indicated the certainty of the estimated effect as 'important' or as 'associated with uncertainty' (Figure 1).

Figure 1. Magnitude-based inferences to describe effect estimates, CIs, and clinical relevance for efficacy outcomes. The range of equivalence is defined as a risk ratio of 0.8 to 1.25.



For safety outcomes such as any SAE, any AE, and all class-specific side effects, we defined the clinically important size of benefit as RR of 0.90 and the reciprocal as clinically important harm (RR 1.11) with a 'range of equivalence' of 0.9 to 1.11 (Figure 2). Effects lower than 0.90 and larger than 1.11 were considered to be clinically important.

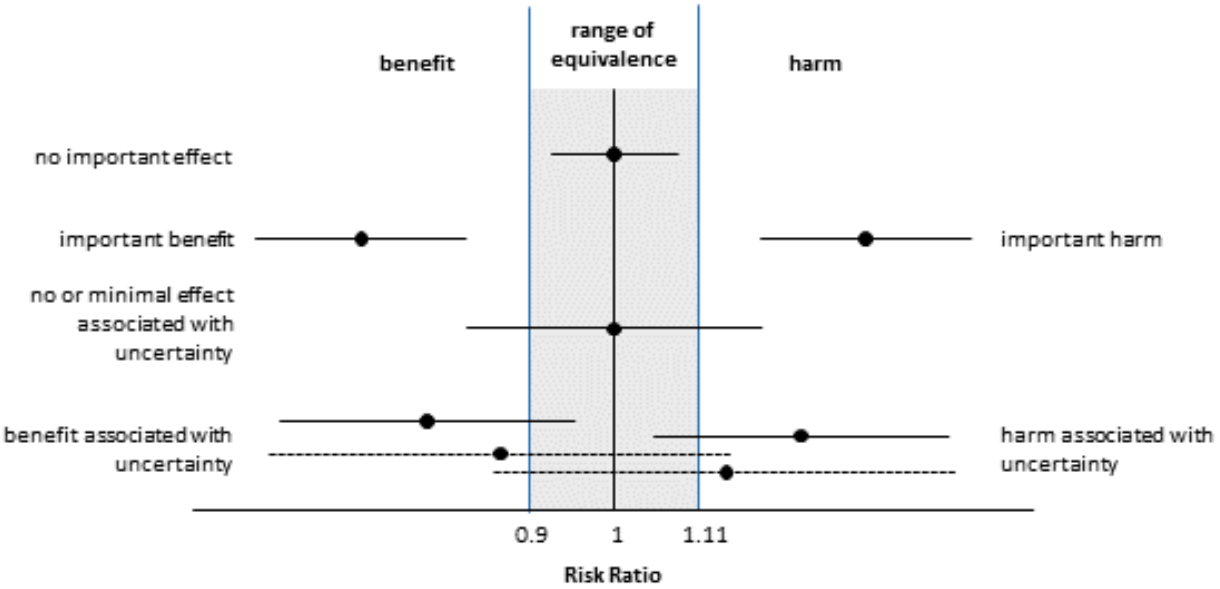
Figure 2. Magnitude-based inferences to describe effect estimates, CIs, and clinical relevance for safety outcomes. The range of equivalence is defined as a risk ratio of 0.9 to 1.11.



The 'range of equivalence' is presented in all forest plots and is indicated by blue border lines crossing RR 0.8/0.9 and RR 1.25/1.11 (efficacy/safety outcomes). We used the function forest of the R package netmeta version 1.0-1 for analysis and for visualization of the 'range of equivalence' (netmeta; Rücker 2019).

Unit of analysis issues

Cluster-randomized trials

We did not include cluster-randomized trials.

Cross-over trials

We did not include trials with cross-over design.

Studies with multiple treatment groups

We included multi-arm studies in the data set as a series of two-arm comparisons. To reflect the fact that comparisons within multi-arm studies are correlated, we adjusted the standard error of each two-arm comparison from a multi-arm study. We used the method proposed by Rücker and Schwarzer, which uses back-calculated standard errors in the weighted least-square estimator to reflect the within-study correlation (Rücker 2012; Rücker 2014; Rücker 2015).

Studies with zero events

We included in the analysis studies with zero events in one or more arms. We applied the constant continuity correction approach (continuity correction 0.5) as described by Sweeting 2004, using the R package netmeta version 1.0-1 for analysis (netmeta).

Dealing with missing data

We noted levels of attrition for included studies in the 'Risk of bias' table as part of the Characteristics of included studies. We did not request from trial authors missing participant outcome data to reduce the workload and to enhance the feasibility of the review being completed in a reasonable time frame.

We carried out analyses for efficacy outcomes, as far as possible, on an intention-to-treat (ITT) basis. For the analysis of safety, we carried out as-treated analysis as far as possible (and we were ready to accept if the randomization was broken).

In cases of missing data, we used an 'available-case analysis' by excluding from the analysis all participants for whom the outcome is missing.

Assessment of heterogeneity

Assessment of clinical and methodological heterogeneity within treatment comparisons

We planned to use descriptive statistics of parameters reported in the Characteristics of included studies table to assess whether the studies within each pair-wise comparison are homogenous enough with respect to potential effect modifiers (such as risk of bias, intervention details, and funding source), so that the assumption of homogeneity might be plausible. For the effect modifiers 'risk of bias' and 'dose of intervention', we accepted heterogeneity (see inclusion criteria of this review) and assessed the impact of these effect modifiers via sensitivity analysis for 'risk of bias' and subgroup analysis for 'dose of intervention'. Due to the quantity of data and the lack of information for the effect modifier 'funding source' in many studies, an objective and reliable assessment of the distribution of this effect modifier within all comparisons was not possible. In general, we assumed that for all included studies, the study populations, interventions, outcomes, and study settings matched the inclusion criteria of the current systematic review.

Assessment of transitivity across treatment comparisons

We planned to assess the assumption of transitivity by comparing the distribution of potential effect modifiers (see Appendix 3: 'Potential effect modifiers') across the different pair-wise comparisons. In the case of intransitivity (e.g. substantially imbalanced distribution of effect modifiers among comparisons),

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

we planned to not perform NMA. For the effect modifiers 'risk of bias' and 'dose of intervention', we accepted differences in the distribution of these effect modifiers across treatment comparisons (see inclusion criteria of this review) and assessed the impact of these effect modifiers via sensitivity analysis for 'risk of bias' and subgroup analysis for 'dose of intervention'. Due to the quantity of data and the lack of information for the effect modifier 'funding source' in many studies, an objective and reliable assessment of the distribution of this effect modifier within all comparisons was not possible. In general, we assumed that for all included studies, the study populations, interventions, outcomes, and study settings matched the inclusion criteria of the current systematic review.

Assessment of reporting biases

When we identified 10 or more relevant studies, we investigated risk of bias across studies (such as publication bias) in pair-wise meta-analyses ('Interventions of direct interest', primary outcomes) using funnel plots. If funnel plot asymmetry was suggested by a visual assessment, we performed exploratory analyses (e.g. Rücker's arcsine test for dichotomous data, contour-enhanced funnel plots, trim and fill sensitivity analyses) to further investigate funnel plot asymmetry. We analysed reporting bias using the R package meta version 4.9-7 (meta).

Data synthesis

We used standard pair-wise meta-analysis and NMA for synthesizing information from numerous studies addressing the same outcomes but involving different interventions.

Methods for pair-wise meta-analyses and network meta-analyses

We performed standard pair-wise meta-analyses for all primary outcomes and substance class-specific side effects using a random-effects model (inverse variance weighting) in RevMan for each treatment comparison (drugs of primary interest versus placebo) with at least two studies. We reported the results in the Data and analyses section. We did not report the results in the Effects of interventions section to reduce the amount of information presented.

For NMAs, we used a frequentist approach based on the graph-theoretical method of Rücker et al (Rücker 2012). We performed random-effects NMAs for all outcomes in R using the package netmeta version 1.0-1 (netmeta; Rücker 2014). We separated mixed treatment evidence into direct and indirect evidence using the function netsplit from this package.

We reported all NMA, direct, and indirect estimates of all outcomes in supplementary files to reduce the amount of information provided in the text. In the Effects of interventions section, we presented only the following selection of NMA estimates of the primary analyses on the outcome level. First, we summarized the range of NMA effects for both drug combinations and single drugs with important clinical effects. Second, we summarized the range of NMA effects of all drug combinations and all single drugs (independent of the direction of effects). In the range of effects, we specified the most effective and the least effective drug or drug combination.

Methods for analysing additive effects of drug combinations

The primary NMA treated all single drugs and all combination prophylaxes as different nodes in the network. We performed a second analysis based on the assumption that the effects of combined treatments (e.g. A + B, A + B + C, B + C) are additive sums of their components. This assumption, together with the network structure, leads to a statistical model that allows decomposing the observed relative effects into the single components and estimating the effects of the components. The hypothesis of additivity can be tested by comparing estimates from this model with those from the primary analysis (Mills 2012). We used the function netcomb of the R package netmeta version 1.0-1 for analysis (netmeta; Rücker 2019).

Subgroup analysis and investigation of heterogeneity

Assessment of statistical heterogeneity

Assumptions when estimating the heterogeneity

In NMA, we assumed the same heterogeneity across the different comparisons. In standard pair-wise meta-analyses, we assumed the common heterogeneity variance estimated from the NMA for each pair-wise comparison.

Measures and tests for heterogeneity

We assessed heterogeneity by the common between-trial variance measure (tau^2), the Q-statistics, the I^2 statistic, and the 95% prediction interval (95% PI). The 95% PI shows where the true effect of a new study similar to the existing studies is expected to lie (Riley 2011). For interpretation of heterogeneity, we compared the 95% PI and the 95% CI of the NMA treatment estimate with respect to the range of clinically relevant effect sizes and the range of equivalence.

Assessment of statistical inconsistency (incoherence)

Inconsistency (incoherence) is the statistical manifestation of intransitivity that occurs when the direct and indirect estimates in a network of treatments do not agree. The distinction between intransitivity and inconsistency (incoherence) is analogous to the distinction between clinical (or methodological) heterogeneity and statistical heterogeneity in standard pair-wise meta-analysis (Cipriani 2013).

At a global level, we assessed heterogeneity and inconsistency (incoherence) of the whole network by decomposing the Q-statistic into variation of the effect estimates within designs (heterogeneity) and between designs (inconsistency) (Higgins 2012; Krahn 2013). A design is each combination of treatments within a study in a network meta-analysis (e.g. for treatments A, B, and C, possible designs are A:B, A:C, B:C, and A:B:C). In addition, we used the full random-effects design-by-treatment interaction model to assess whether all interventions behave similarly in all comparisons. We used the R package netmeta for Q decomposition and for calculation of the full random-effects design-by-treatment interaction model (netmeta).

At a local level, we assessed differences between direct and indirect effect estimates of specific comparisons (incoherence) using descriptive Z-tests and clinical relevance of the effect estimates. However, only clinically relevant incoherence based on different clinical conclusions of the 95% CI of direct and indirect treatment effect estimates with respect to the range of equivalence was used for interpretation of incoherence.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Investigation of heterogeneity

In cases of statistical heterogeneity (Q-test with P < 0.05, 95% PI compared to 95% CI) within treatment comparisons, we explored possible sources (Higgins 2019). We restricted these explorative analyses to primary and GRADE-relevant secondary outcomes and to the effect modifier 'dose of the intervention' as potential sources of heterogeneity. For pair-wise comparisons (drugs of direct interest versus placebo), we performed subgroup analyses in RevMan. For the network, we used the R package netmeta to carry out separate analyses for the subgroups (netmeta).

Different treatment regimens—subgroup analysis of doses

Because it is of interest for clinicians and patients to know the optimal dose of antiemetic drugs with respect to efficacy and safety, we performed subgroup analyses.

We excluded combinations of drugs from the subgroup analysis because we cannot be sure whether some combinations can affect the dose effects. We performed the subgroup analysis of doses in the network with single drugs only (see 'Sensitivity analysis—Single drugs only') if the effect estimates remained robust compared to the primary analysis.

We separated different doses of the same drug into low, recommended, and high doses (Table 1). We restricted splitting of doses to single drugs of direct interest. The recommended doses or dose ranges for drugs are based on those reported in the 'consensus guidelines for the management of postoperative nausea and vomiting' (Gan 2014). For emerging substances, we used doses or dose ranges based on dose-finding studies (e.g. for amisulpride, see Kranke 2013; no data are available for fosaprepritant).

We categorized the spectrum of available fixed doses into low, recommended, and high doses according to the following algorithm.

- If a single dose X is recommended (Gan 2014), we defined X as the 'recommended dose'; 'low dose' as < X; 'high dose' as > X (lower and upper limits are defined only if reported in Gan 2014).
- If a dose range X to Y is recommended (Gan 2014), we defined X to Y as 'recommended dose range'; 'low dose' as < X; 'high dose' as > Y (lower and upper limits are defined only if reported in Gan 2014).

If flexible doses (e.g. mg/kg) were reported, we transformed flexible doses into fixed doses by multiplying the flexible dose by the mean/median weight of participants reported in the published study (if the weight was not reported, we assumed 70 kg).

Drugs without any dose recommendation according to Table 1 (fosaprepitant, scopolamine) and drugs not of direct interest were included in the analysis. In these cases, all doses of the same drug were lumped together in a dose category 'NA'.

If there were studies that used drugs of direct interest that were not attributable to any dose category in Gan 2014 (e.g. using different application routes), we excluded these studies from the subgroup analysis. Exclusion of these studies was necessary for subsequent analyses of additive dose effects (see 'Methods for analysing additive dose effects') because additional categories that could not assigned to the additive concept may interfere with the analysis.

We used the R package netmeta to carry out network meta-analyses with subgroups (netmeta). Network effect estimates were used for interpretation of subgroup analyses in this review. In addition, studies were divided into subgroups in pair-wise meta-analyses of primary and GRADE-relevant secondary outcomes, and these were reported in the Data and analyses section. We did not report these pair-wise subgroup analyses in the Effects of interventions section to reduce the amount of information provided in review text.

We performed this explorative analysis for all primary and for all secondary outcomes while considering side effects to answer this specific question about effects of the 'dose of the intervention' on effect estimates (Higgins 2019).

We summarized the most commonly used dosages, routes, and time points of administration of single drugs of direct interest for the primary outcome vomiting and reported this information in the Effects of interventions section.

Methods for analysing additive dose effects

We used the subgroup analysis of dose with splitting of drugs into the dose categories low, recommended, and high doses (see 'Different treatment regimens—subgroup analysis dose') as primary NMA. We performed a second analysis based on the assumption that the effects of combined categories (e.g. low + recommended, low + recommended + high, recommended + high) are additive sums of their individual categories. This assumption, together with the network structure, leads to a statistical model that allows decomposing of observed relative effects into single dose categories and estimating the effects of the dose categories. The hypothesis of additivity can be tested by comparing estimates from this model with those from the primary analysis (subgroup analysis dose) (Mills 2012). We used the function netcomb of the R package netmeta version 1.0-1 for analysis (netmeta; Rücker 2019).

Sensitivity analysis

We analysed the robustness of the effect estimates by performing the following sensitivity analyses.

- Risk of bias: including only trials at low risk of bias in the overall risk of bias summary (see 'overall risk of bias summary') and excluding all trials with high or unclear risk of bias in the overall risk of bias summary.
- Imbalance in baseline details: Including only trials with a balanced distribution of baseline details in the study arms and excluding all studies with imbalance in baseline details in the study arms.
- Primary PONV-related outcome: including only trials with a primary PONV-related outcome and excluding trials that analysed the outcomes vomiting and nausea not as primary endpoints.
- Funding source 'industry': including only trials funded by industry and excluding all other studies.
- Funding source 'non-industry': including only trials funded by non-industry resources and excluding all other studies.
- Single drugs only: including only study arms investigating single drugs and excluding study arms investigating combinations of drugs. This analysis compared the robustness of network effect estimates of the primary network meta-analysis and the sensitivity analysis including single drugs only (which is the basic analysis for the subgroup analysis dose).

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

- Comparability of drug doses within studies: there is a possibility that some trials compare one drug at the upper limit of its therapeutic range (e.g. high dose) with another drug at the lower limit of its therapeutic range (e.g. low dose) within the same study. This can lead to an overestimation of the drug used in higher doses. We captured this study characteristic by adding a dichotomous variable indicating whether the dosages are comparable (yes = 1) or not (no = 2) and used this information for sensitivity analysis (Cipriani 2009). Comparable dose categories were low-low, recommended-recommended, and high-high (for definitions of dose categories of individual drugs, see Table 1). In the sensitivity analysis, we included only studies that investigated comparable dose categories of different drugs. This sensitivity analysis was restricted to single drugs only.
- Adverse event monitoring: we used the information on adverse event monitoring of studies to test the robustness of effect estimates for the primary outcomes 'SAE' and 'any AE' by sensitivity analyses. We included only studies with low risk of bias for adverse event monitoring and excluded high and unclear risk of bias studies for adverse event monitoring.

We restricted sensitivity analyses to primary outcomes with the exceptions of 'Risk of bias' and 'Comparability of drug doses within studies', which were relevant for all side effects (GRADE-relevant secondary outcomes).

We reported effect estimates of the sensitivity analyses of drugs of direct interest in the section Effects of interventions if the effect estimates differed from the primary analysis regarding clinical interpretation of the effect (non-robust effect estimates).

Summary of findings and assessment of the certainty of the evidence

We presented the main results of the review in 'Summary of findings' (SoF) tables including a rating of the certainty of evidence as suggested for network meta-analysis by Yepes-Nuñez 2019. The certainty rating was based on the principles of the GRADE Working Group and was assessed by an alternative system developed by Salanti et al (termed CINeMA, Confidence in Network Meta-Analysis, Salanti 2014).

We created one primary and eleven secondary SoF tables. In the primary SoF table, single antiemetic drugs of direct interest (see 'Interventions of direct interest') with important beneficial effect and with high or moderate certainty of evidence for the primary outcome (vomiting) were presented together with all relevant substance class-specific adverse events. For the secondary SoF tables, one table for each outcome (primary outcomes and drug-class important adverse effects) was created, comparing all single drugs of direct interest to placebo.

In the SoF tables we presented NMA relative treatment effects, anticipated absolute effects, ranking of treatments using P scores, and the certainty of evidence.

The quality of the body of the NMA evidence was assessed by two independent reviewers (SW, OJ) and reflects within-study risk of bias (study limitations), across-studies bias (publication bias), indirectness, imprecision, heterogeneity (variability between studies within each comparison), and incoherence (variability between direct and indirect evidence). We have only appraised the certainty of evidence for relative treatment effects and not for treatment rankings.

The clinically important size of effect and not the statistical significance of NMA relative treatment effects was relevant for assessing the certainty of evidence. We defined for efficacy and safety outcomes, a range of relative treatment effects around the line of no effect that do not indicate important clinical difference between the interventions, which is termed the 'range of equivalence'.

- Efficacy outcomes (vomiting 0 to 24 hours): a relevant effect is defined as RR 0.8 (range of equivalence: 0.8 to 1.25)
- Safety outcomes (SAE, any AE, headache, sedation, extrapyramidal symptoms, constipation, postoperative wound infection, arrhythmia, visual disturbances, and QT prolongation): a relevant effect is defined as RR 0.9 (range of equivalence: 0.9 to 1.11)

We GRADEd each network estimate according to the following criteria (details are described in the Appendix 5):

- Within-study risk of bias (study limitations)
- Across-studies bias (publication bias)
- Indirectness
- Imprecision
- Heterogeneity
- Incoherence

The GRADE assessment resulted in one of four levels of certainty and these express our confidence in the estimate of effect (Balshem 2011).

- High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.
- Moderate certainty: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.
- Low certainty: our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.
- Very low certainty: we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.

Certainty of evidence for effect estimates can vary greatly across comparisons within a network, and can range from high to very low certainty. In making inferences regarding the choice of an intervention recognizing the certainty of each comparison is far more valuable than ranking efficacy alone (Puhan 2014).

Reporting guidelines

This review is reported based on the PRISMA Extension Statement for NMA (Hutton 2015) and on the 'Protocol template for a Cochrane Intervention review that compares multiple interventions' from the Cochrane Comparing Multiple Interventions Methods Group (Protocol Template 2014).

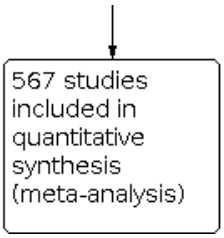
Figure 3. (Continued)



In the first search, we identified 15,600 records through database searching and another 107 by handsearching of reference lists of meta-analyses in the field. In the search update, we identified another 5309 records. In total, 14,640 records remained after duplicates had been removed. These were screened independently by 11 review authors (SW, DM, MR, HMS, AH, DR, ILB, MSS, LHJE, PKr, TS) regarding title and abstract. A total of 1762 remaining records were selected and assessed for eligibility by reviewing the full texts and protocols; 690 records did not fulfil the eligibility criteria and had to be excluded. A total of 245 studies (252 records) were awaiting classification. Of these, 206 studies were awaiting classification due to missing information in the study reports or study protocols, and 39 were identified as potentially eligible studies after the first search date (these studies will be fully included in the next review update). An additional 88 study protocols of the World Health Organization International Clinical Trials Registry Platform (WHO ICTRP) database identified in the search update were awaiting classification (until the next review update) because the database was closed at the time of the search update. All protocols were listed in a supplementary file (Supplementary File_ICTRP-protocols). Finally, 732 records (full-text primary and secondary study reports, abstracts, and protocols), which could be allocated to 585 studies, were included in the qualitative synthesis, and 567 of these studies were used to perform the pair-wise and network meta-analyses. Eighteen studies could not be used for analysis, although they reported outcomes of interest for this review. These studies did not report data in a way that could be used for analysis.

Eighty-three of 585 studies (14%) were not published in English. Twenty-seven studies were published in Korean (Ahn 2002; Choi 1999; Choi 2008; Joe 2009; Kil 1999; Kim 1992; Kim 1999; Kim 2000; Kim 2001; Kim 2005a; Kim 2005b; Kim 2007; Kim 2012; Kim JE 2005; Koo 2001; Lee 2008b; Lee HS 2004; Lee SY 2001; Lee YC 2009; Moon 2010; Park 2006; Rho 2001-1; Ryu 2007; Seo 2003; Suh 2007; Yoon 2009; Yoon 2016), 14 in German (Alon 1982; Biedler 1998; Eberhart 1999b; Heinke 1996-1; Lutz 1969; Morin 1999; Muller 2003; Piper 2003; Ploner 1997; Rusch 1999; Rusch 2002; Schuh 1987; Tolksdorf 1986; Triem 1999), 11 in Turkish (Akin 2005; Akkaya 2001; Altunkaya 2003; Cekmen 2003; Cubukcu 2007; Guldogus 1994; Karabayirli 2003; Kaya 2000; Ozdamar 2006; Ozunlu 2005; Tezcan 1993), eight in Spanish (Agamez Medina 2015; Alonso Damian 2012; Cabrera 1997; Delas Ramirez 2001; Perez Ascencio 1992; Perez Garcia 2000; Pertusa 1996; Sanduende 2007), seven in Chinese (Jin 2013; Li 2015-1; Liu 2011; Quan 2007; Quan 2011; Wang 1995; Zhu 2010), three in Italian (Pascucci 1996; Rettori 2011; Stefani 1995), three in Persian (Heidari 2015b; Hemmati 2014; Safae 2011), two in French (Badaoui 1998; Badaoui 1999), two in Russian (Gallinger 2007; Ionescu 2007), and one each in Bulgarian (Dimov 2004), Danish (Jespersen 1989), Dutch (Gijzels 2006), Greek (Kanakoudis 1985), Japanese (Seki 2005), and Portuguese (Martins 1995).

We did not include in our systematic review any abstracts lacking a published full-text study report. We included six studies that were not published in a journal but were presented as publicly available study reports with results (NCT00888329; NKO101287; NKT102245; NKT102260; NKT102552; PALO-04-07).

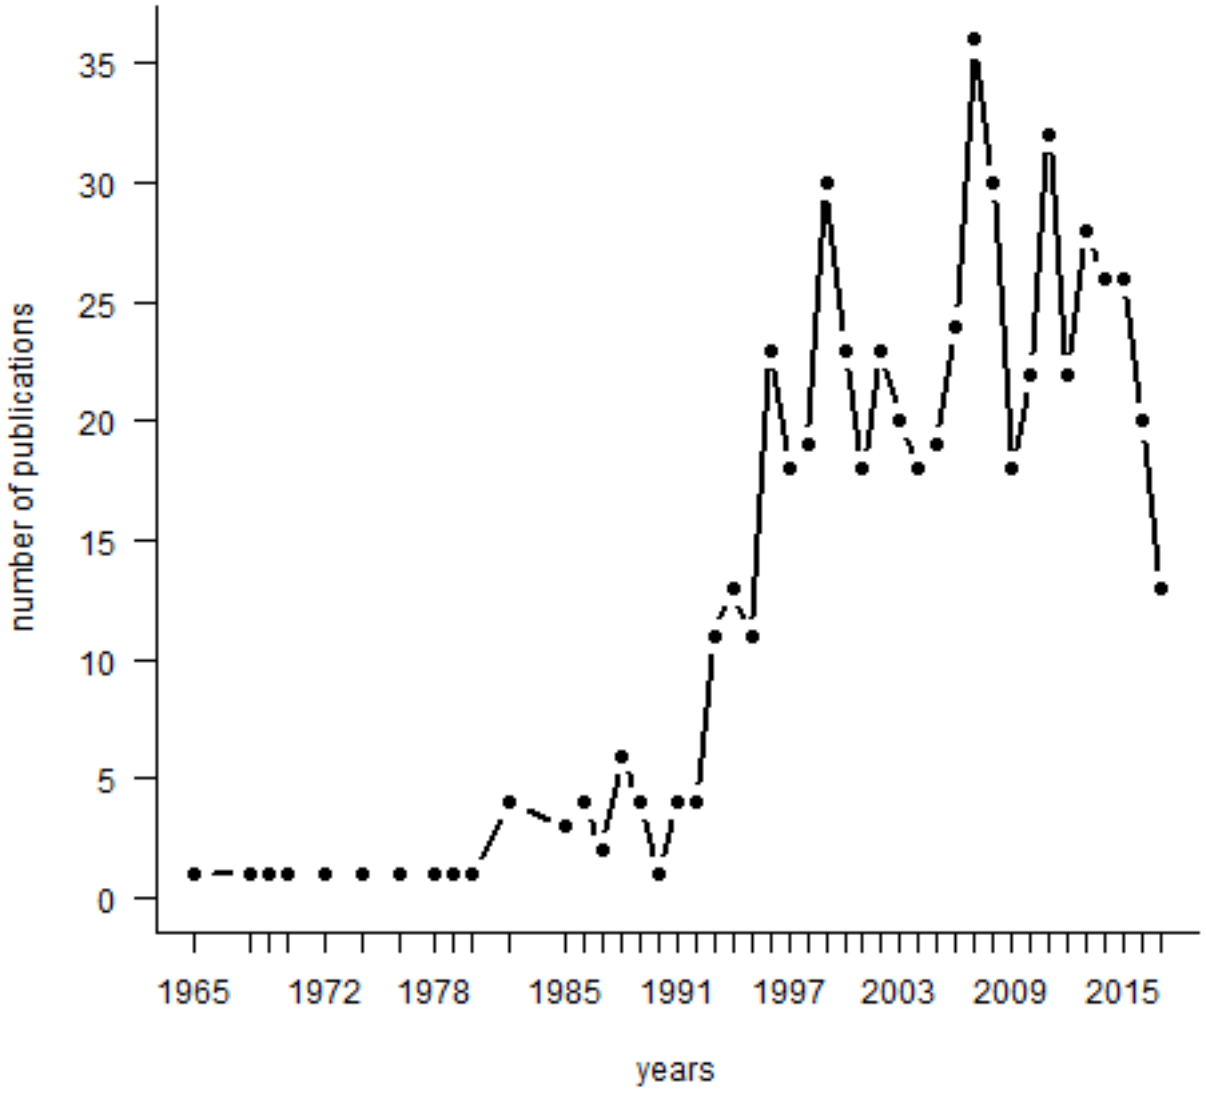
Included studies

We included 585 studies (733 records) in this systematic review. Three publications included two different studies (Gesztesi 2000-1; Gesztesi 2000-2; White 2005-1; White 2005-2; White 2007-1; White 2007-2). Six studies included two different anaesthesia regimens (inhalational and propofol anaesthesia), and we divided the participant population into several sub-studies for analysis only (Apfel 2004-1; Apfel 2004-2; Heinke 1996-1; Heinke 1996-2; Li 2015-1; Li 2015-2; Rho 2001-1; Rho 2001-2; Voigt 2011-1; Voigt 2011-2; Zhang 2013-1; Zhang 2013-2). We could allocate 83 study protocols to 75 included studies. Forty-five studies were published more than once. A total of 64 records were multiple publications of clinical studies in abstract format or as a journal publication.

The included studies were published between 1965 (Khanna 1965) and 2017 (Bang 2017; Bjerregaard 2018; Corcoran 2017; Cortes Flores 2018; Gan 2017; Hu 2017; Kizilcik 2017; Koyuncu 2017; Monohar 2017; Mujoo 2017; Satomoto 2017; Song 2017; Yang 2017). A majority of included studies (71%) were published in the last two decades between 2000 and 2017. The number of RCTs increased over time, reaching a peak of publications in 2007 with 36 (36/585; 6%) published trials (Figure 4). From 1996 to 2016, more than 15 trials were published annually (Figure 4).

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Figure 4. Number of annual publications (included studies, n = 585) from 1965 to 2017 (first search).



The included studies provide data on 97,516 randomized participants, of which data on 93,211 were analysed. A detailed description of the trials can be found under Characteristics of included studies.

Comparators

This review compared 21 single interventions of direct interest and 23 additional single interventions to supplement the analysis. All interventions are listed in Types of interventions. Of 585 included studies, 541 studies (93%) investigated drugs of direct interest, 19 studies investigated drugs not of direct interest, and 25 studies investigated both types of interventions.

A total of 384 studies (66%) included an inactive control arm (placebo or no treatment) in the study design. Active interventions only were compared in 201 studies (34%). The number of eligible study arms in included trials ranged between two and 16. In summary, 310 studies (53%) investigated two groups, 160 studies (27%) three groups, 77 studies (13%) four groups, 23 studies (4%) five groups, 11 studies (2%) six groups, two studies (0.3%) seven groups, and two studies more than seven groups (Apfel 2004-1; Apfel 2004-2; Beattie 1993).

A total of 423 studies (72%) investigated only single drugs, 31 studies (5%) compared only combinations of drugs, and 131 studies (23%) compared both single drugs and combinations of drugs.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

The top 10 of the most investigated antiemetic drugs administered as single prophylaxis for prevention of PONV in this review were ondansetron (246 studies), dexamethasone (120 studies), droperidol (97 studies), metoclopramide (76 studies), granisetron (51 studies), ramosetron (38 studies), palonosetron (35 studies), tropisetron (32 studies), dolasetron (20 studies), and scopolamine (18 studies). Thus, the 5-HT_3 receptor antagonists are the most widely studied substance class in this review. Other drugs of direct interest administered as single interventions were much less studied, with 10 studies for haloperidol, seven studies for aprepitant and promethazine, five studies for dimenhydrinate and methylprednisolone, three studies for fosaprepitant, two studies for amisulpride, casopitant, and perphenazine, and one study for rolapitant. No eligible study was found that investigated meclizine as a single intervention.

Among the combinations of drugs, two-fold combinations were investigated in 159 studies, three-fold combinations in eight studies (Apfel 2004-1; Benevides 2013; Bergese 2016; DeOliveira 2011; Gallinger 2007; Liu 2011; Long 2014; Tang 2003), and one four-fold combination in one study (Hammas 2002). Forty-three different two-fold combinations were used in the included studies. Four of these two-fold drug combinations were used in 10 or more studies (54 times: dexamethasone-ondansetron, 20 times: dexamethasone-granisetron, 15 times: droperidol-ondansetron, 10 times: dexamethasone-metoclopramide). A total of seven different three-fold drug combinations were investigated, of which dexamethasone-droperidol-ondansetron was used most often in four of eight studies (Apfel 2004-1; Gallinger 2007; Liu 2011; Tang 2003). The other six three-fold combinations were investigated once each (aprepitant-dexamethasone-ondansetron, aprepitant-dexamethasone-promethazine, dexamethasone-dolasetron-droperidol, dexamethasone-haloperidol-ondansetron, dexamethasone-metoclopramide-ondansetron, dexamethasone-ondansetron-promethazine). The only investigated four-fold drug combination was dexamethasone-droperidol-metoclopramide-ondansetron.

Details of interventions

We recorded doses, administration time points, and application routes for all interventions administered as single drugs. We categorized doses of drugs that are of direct interest into low, recommended, and high doses according to Table 1. We categorized time points of administration into before anaesthesia, at induction of anaesthesia, during surgery, and at end of surgery. We differentiated between intravenous, oral, intramuscular, and other routes of administration (e.g. epidural, intranasal).

Eighty studies (14%) investigated different doses of the same antiemetic drug, 12 studies (2%) different administration time points, and nine studies (2%) different routes of application.

5-HT_3 receptor antagonists

Dolasetron (20 studies) was administered intravenously or per oral at doses of 12.5 to 100 mg (recommended to high) and 25 to 200 mg (no dose recommendation available), respectively. Most of the study arms (56%) investigating intravenous dolasetron used high doses (> 12.5 mg). Intravenously administered dolasetron was given at induction of anaesthesia (22%) or at end of surgery (78%). Oral dolasetron was administered before anaesthesia.

Granisetron (51 studies) was mainly administered via the intravenous route at doses of 0.1 to 4 mg (low to high). Most of the study arms (84%) investigating intravenous granisetron used recommended doses (0.35 to 3 mg). Intravenous granisetron was given at all different time points ranging from before anaesthesia to end of surgery. Granisetron was administered orally before anaesthesia at doses of 2 mg in one study (Bhatnagar 2007).

Ondansetron (246 studies) was administered via the intravenous or oral route at doses of 1 to 16 mg (low to high) and 4 to 16 mg (low to high), respectively. In most of the study arms (71%) investigating intravenous ondansetron, recommended doses were used. Low and high doses of intravenous ondansetron were used in 9% and 25% of study arms, respectively. Intravenous ondansetron was administered most often at induction of anaesthesia (69%) and at end of surgery (26%). Oral ondansetron given before anaesthesia was investigated in 32% of study arms at low doses, in 47% at recommended doses, and in 21% at high doses.

Palonosetron (35 studies) was administered only via the intravenous route at doses of 0.007 to 2.169 mg (low to high). In most of the study arms, palonosetron was used at recommended doses (69%), followed by study arms using low doses (21%). Administration at induction of anaesthesia was used most often (69%), followed by administration at end of surgery (28%).

Ramosetron (38 studies) was administered intravenously or per oral at doses of 0.1 to 0.45 mg (low to high) and 0.1 mg (no dose recommendation available), respectively. Most study arms (89%) investigating intravenous ramosetron used recommended doses. Administration of intravenous ramosetron at end of surgery was used most often (67%), followed by administration at induction of anaesthesia (28%). Oral ramosetron (three studies) was administered before anaesthesia.

Tropisetron (32 studies) was administered intravenously or per oral at doses of 0.5 to 7.25 mg (low to high) and 5 mg (no dose recommendation available), respectively. Most study arms investigating intravenous tropisetron used high doses (69%), followed by recommended doses (25%). Administration of intravenous tropisetron at induction of anaesthesia was used most often (75%), followed by administration at end of surgery (19%). Oral tropisetron (three studies) was administered before anaesthesia.

D_2 receptor antagonists

Amisulpride (two studies) was administered only via the intravenous route at induction of anaesthesia at doses of 1 to 20 mg (low to high).

Droperidol (97 studies) was administered mainly intravenously at doses of 0.25 to 7.5 mg (low to high). In addition, intramuscular (Rothenberg 1991; Tezcan 1993; Verhasselt 1988), epidural (Lee 2000; Lee IH 2007), and acupoint injection—Jin 2013; Zhu 2010—were tested at doses of 2.5 to 5 mg (no dose recommendation available). Patton 1974 injected droperidol via intravenous (1.25 mg) and intramuscular routes (3.75 mg) shortly after the start of surgery. Two studies did not report the route of administration (Nesek Adam 2004; Prescott 1976). Most study arms investigating intravenous droperidol used recommended doses (57%), followed by high doses (37%). Intravenous low-dose droperidol was investigated in 6% of study arms. Intravenous droperidol was given at all different time points ranging from before anaesthesia to end

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

of surgery. However, administration at induction of anaesthesia of intravenous droperidol was used most often (73%), followed by administration at end of surgery (18%). Intramuscular droperidol was administered before anaesthesia or at end of surgery. Epidural droperidol was administered at end of surgery. Droperidol injected into the acupoint was administered before or at induction of anaesthesia.

Haloperidol (10 studies) was administered mainly intravenously at doses of 1 to 2 mg (recommended to high). In addition, one study investigated intramuscular injection of 2 mg haloperidol at end of surgery (Feng 2009), and another study did not report the route and time point of administration (Judkins 1982). Most study arms investigating intravenous haloperidol used high doses (63%), followed by recommended doses (37%). Administration of intravenous haloperidol at induction of anaesthesia was used most often (75%), followed by administration at end of surgery (25%).

Metoclopramide (76 studies) was administered mainly intravenously at doses of 7 to 38.4 mg (low to recommended). In most study arms, intravenous metoclopramide was used at low doses (97%). Two studies used intravenous metoclopramide at recommended doses (Derbent 2005; Talesh 2011). In addition, intramuscular—Huseyinoglu 2016—and intranasal injections —Wagner 1996—were tested at doses of 10 and 20 mg (no dose recommendation available), respectively. One study did not report the route of administration (Nesek Adam 2004). Administration of intravenous metoclopramide at induction of anaesthesia was used most often (60%), followed by administration at end of surgery (35%). Oral metoclopramide was given before anaesthesia.

Perphenazine (two studies) was administered only via the intravenous route at induction of anaesthesia at the recommended dose of 5 mg (Desilva 1995; Steinbrook 1998).

NK_1 receptor antagonists

Aprepitant (seven studies) was administered only via the oral route before surgery at doses of 40 to 125 mg (recommended to high). In most of the study arms (66%), aprepitant was used at high doses, followed by study arms using recommended doses (33%).

Casopitant (two studies) was administered only via the oral route before surgery at the recommended dose of 150 mg.

Fosaprepitant (three studies) was administered only via the intravenous route at induction of anaesthesia at doses of 150 mg (no dose recommendation available).

Rolapitant (one study) was administered only via the oral route before surgery at doses of 5 to 200 mg (low to recommended).

Corticosteroids

Dexamethasone (120 studies) was administered mainly intravenously at doses of 1.25 to 35 mg (low to high). In addition, oral administration (Eberhart 2006; Ozdamar 2006), epidural injection (Hefni 2014; Khafagy 2010), and perineural injection—Tomar 2017—were tested at doses of 4 to 8 mg (no dose recommendation available). One study did not report the route of administration (Heidari 2015b). Most study arms investigating intravenous dexamethasone used high doses (69%), followed by recommended doses (27%). Intravenous low-dose dexamethasone was investigated in 4% of study arms. Intravenous dexamethasone was given at all different time points ranging from before anaesthesia to end of surgery. However, administration at induction of anaesthesia was used most often (77%), followed by administration before anaesthesia (13%) and at end of surgery (8%). Epidural and perineural dexamethasone were administered at induction of anaesthesia; oral dexamethasone was given before anaesthesia.

Methylprednisolone (five studies) was administered intravenously at doses of 40 to 125 mg (recommended to high), intramuscularly at doses of 40 mg (no dose recommendation available), and interarticularly at doses of 40 mg (no dose recommendation available). Intravenous injection was administered at induction of anaesthesia, intramuscular injection was administered at induction of anaesthesia or at end of surgery, and intra-articular injection occurred during surgery.

Antihistamines

Dimenhydrinate (five studies) was administered intravenously at doses of 50 mg (low), intramuscularly at doses of 50 mg (no dose recommendation available), and per oral at doses of 75 mg (no dose recommendation available). Intravenous injection was administered at induction of anaesthesia; intramuscular injection and oral application were performed before anaesthesia.

Promethazine (seven studies) was administered intravenously at doses of 5.6 to 56.5 mg (low and high), intramuscularly at doses of 25 mg (no dose recommendation available), and per oral at doses of 20 mg (no dose recommendation available). Intravenous injection was administered at induction of anaesthesia or at end of surgery, intramuscular promethazine was administered at end of surgery, and oral application was performed before anaesthesia.

No eligible study was found that investigated meclizine as a single intervention.

Anticholinergics

Scopolamine (18 studies) was administered mainly via a transdermal patch before anaesthesia at doses of 0.5 to 1.5 mg (recommended to high). Five studies did not report the dose of transdermally administered scopolamine (Schuh 1987; Semple 1992; Stromberg 1991; Tolksdorf 1986; Wilkinson 1989). In addition, one study investigated an intramuscular injection of 0.46 mg scopolamine before anaesthesia (Larsson 1988), and two studies investigated the oral route of scopolamine at doses of 0.3 to 0.6 mg (Baxendale 1993; Simpson 1988). Two studies did not report the route of administration (Heidari 2015b; Shah 1972).

Anaesthesia and surgical procedures

In 515 studies (88%), participants were anaesthetized through inhalational anaesthesia techniques based on volatiles alone (sevoflurane, isoflurane, desflurane, etc.), a balanced anaesthesia regimen (volatile with opioid), or a combined regimen (volatile with propofol). Total intravenous anaesthesia (TIVA) was used in 56 studies (10%). Six studies used both inhalational anaesthesia and TIVA in the study design, and we divided participant populations into sub-studies for analysis according to the anaesthesia regimen used (Apfel 2004-1; Apfel 2004-2; Heinke 1996-1; Heinke 1996-2; Li 2015-1; Li 2015-2; Rho 2001-1; Rho 2001-2; Voigt 2011-1; Voigt 2011-2; Zhang 2013-1; Zhang 2013-2). Eight studies did not specify which type of anaesthesia was used, but it was reported that anaesthesia was standardized for all participants within the individual studies (Alia 2015; Backes 2013; Barrow 1994; Gesztesi

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

2000-1; Gesztesi 2000-2; Khan 2006; Kumar 2013; NCT00888329; Thimmasettaiah 2012). The overall mean duration of anaesthesia for all studies was 108 minutes. The overall median duration of anaesthesia was 101 minutes with an interquartile range of 68 to 140 minutes. The shortest mean duration of anaesthesia reported in a study was 1.72 minutes (Ali Melkkila 1996), and the longest mean duration of anaesthesia was 486 minutes (Tsutsumi 2014).

In 189 studies (32%), gynaecological procedures were most common, followed by gastrointestinal (19%) and miscellaneous procedures (18%). The latter included unspecified abdominal surgery, unspecified plastic surgery, and multiple surgery types within individual studies. Participants were undergoing otolaryngological procedures in 36 studies (6%), endocrine surgery including thyroidectomy in 35 studies (6%), breast surgery including plastic breast surgery in 24 studies (4%), any unspecified laparoscopic procedure in 19 studies (3%), ocular surgery in 13 studies (2%), neurological procedures including spine surgery in 13 studies (2%), orthopaedic surgery in 11 studies (2%), dental procedures in nine studies (2%), cardiovascular and thoracic procedures in four studies (1%), and urological surgery in three studies (1%). In 10 studies (2%), the surgical procedure was not specified.

Population baseline details

The overall mean age of populations in all included studies in this review was 42.4 years, and the median age was 42.5 years. Thirty-four studies (6%) reported a low mean age between 18 and 29 years, and 15 studies (3%) reported a high mean age of more than 60 years. Thirty studies (5%) did not report the mean age of the study population. Most of the included participants were women (83%). In 412 studies (70%), included participants were healthy individuals (American Society of Anesthesiologists (ASA) 1 and 2). In 100 studies (17%), participants were eligible with substantial physical and functional limitations (ASA > 2). In 73 studies (12%), ASA physical health status was not reported.

We collected study population data on the four risk factors for PONV according to Apfel (female gender, non-smoker status, history of PONV or motion sickness, postoperative opioid use). Females only were included in 292 studies (50%), whereas four studies (< 1%) included only males. In 93 studies (16%), a balanced gender distribution with 40% to 60% females was reported. Twenty-seven studies (5%) did not report the gender distribution. A non-smoking status of 100% in the study population was reported in 55 studies (9%). Only active smoking participants were included in one study (Jo 2012). In 399 studies (68%), the smoking status of the study population was not reported. A history of PONV or motion sickness in 100% of the study population was reported in five—Altorjay 2011; Dagtekin 2009; Kim SH 2013; Koivuranta 1999; Pan 2008—and four studies—Altorjay 2011; Dagtekin 2009; Kim SH 2013; Pan 2008—respectively. Exclusion of participants with history of PONV or motion sickness was reported in 100 (17%) and 104 (18%) studies, respectively. In 266 (45%) and 299 studies (51%), respectively, no details on participant history of PONV and motion sickness were reported. In 514 studies (88%), participants received perioperative opioids. In 15 studies (3%), no perioperative opioids were used. For 153 studies (26%), data were provided for all four risk factors. High-risk populations with participants having three and four risk factors at 100% (inclusion criteria) were studied in five—Altorjay 2011; Dagtekin 2009; Kim SH 2013; NKT102552; Pan 2008—and 31 studies, respectively—a total of 6% of all studies. Two risk factors at 100% (inclusion criteria) were reported in 242 studies (41%).

Study conduct (location, setting, funding)

A total of 298 studies (51%) were conducted in Asia, followed by Europe with 148 studies (25%) and North America with 96 studies (16%). Eleven studies (2%) were conducted in South America, nine studies (2%) in Africa, and seven studies (1%) in Australia/Oceania. Sixteen studies (3%) were carried out in several countries.

A total of 489 studies (84%) were conducted at a single centre, and 60 studies (10%) were conducted at multi-centres. The largest multi-centre study (with 58 study centres) was Morris 1998. In 36 studies (6%), the number of involved studies centres was not reported.

Inpatient participants were included in 409 studies (70%), and outpatient participants were included in 103 studies (18%). Twenty-one studies included both inpatient and outpatient participants, and 52 studies (9%) did not report this study setting.

A total of 97 studies (17%) have reported that they were funded by industry, and 104 studies (18%) have reported that they were funded by non-industrial resources. A majority of studies with a total of 384 studies (66%) have not declared any details on funding of the study.

Sample size

The mean sample size of all studies was 167 participants, and the median sample size was 100, with an interquartile range of 70 to 160 participants. The smallest sample size reported in a study was 20 participants with two study groups (Seki 2005), and the largest randomized sample size was 5199 participants with 16 study arms (Apfel 2004-1; Apfel 2004-2). A total of seven studies included more than 1000 participants (Apfel 2004-1; Fortney 1998; Hechler 2001; Morris 1998; Pearman 1994; Philip 2000; Scuderi 2001).

Study focus and reported outcomes

The titles of the studies indicated that 516 studies (88%) had a focus on PONV research. The titles of 69 studies (12%) did suggest a focus other than PONV research. Most of these studies (33%) investigated dexamethasone on postoperative recovery.

A total of 309 studies (53%) explicitly specified a primary study outcome(s) or provided a sample size calculation for one specific outcome. A total of 86% of these primary outcomes were PONV, nausea, or vomiting, and 14% were not PONV-related. A total of 276 studies (47%) have not specified which reported outcome was the primary outcome and did not provide any sample calculation.

A total of 522 studies (89%) investigated relevant efficacy outcomes for this review. In 327 studies (56%), relevant safety outcomes were reported. Eighteen studies (3%) did not report numerical data that can be used in meta-analyses for this review (Aasboe 1998; Altunkaya 2003; Asadollah 2014; Barros 2013; Barrow 1994; Cubukcu 2007; Derbent 2005; Forrester 2007; Gupta 2011; Judkins 1982; Khanna 1965; Kim WJ 2013; Mohammadi 2007; Ozdamar 2006; Ploner 1997; Sniadach 1997; Turner 2004; Vale 2011). These studies provided general statements on relevant safety outcomes.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Excluded studies

We excluded 673 articles (690 records) after reviewing the full texts. Reasons for exclusion are listed under Characteristics of excluded studies. The most common reason for exclusion was a wrong administration time point of the interventions (after the occurrence of PONV, therapeutic not prophylactic intention) with a total of 136 studies (19%), followed by abstracts with 89 studies (13), non-clinical study reports (editorials, commentaries, narrative reviews) with 80 studies (12%), wrong outcomes with 76 studies (11%), paediatric or mixed populations (adults and children) with 68 studies (10%), regional or sedative anaesthesia with 57 studies (8%), wrong study design with 48 studies (7%), wrong or no eligible comparator with 42 studies (6%), different baseline anaesthesia regimens in study arms with 31 studies (5%), wrong intervention with 29 studies (4%), wrong population with seven studies (1%), retracted studies (e.g. authored by Fujii) or notes to retracted studies with six studies (1%), and meta-analysis with four studies (1%).

Studies awaiting classification

A total of 245 studies (252 records) are awaiting classification. Of these, 185 studies were identified during the first search in 2017, with 86 studies reported as full-text journal publications and 99 as study protocols posted on either ClinicalTrials.gov or WHO ICTRP. The other 60 studies were identified after the first search or during the search update in 2020. Thirty-nine of these 60 studies will be fully included in the next review update, and 21 studies are awaiting classification due to missing study information. Details on studies awaiting classification are listed in the Characteristics of studies awaiting classification tables.

Of the 86 studies identified in the first search and reported as journal publications, no full text was available for 29 studies. Amongst the missing information of studies with full text were lack of population age (19 studies), details on the anaesthesia regimen (11 studies), randomization details (eight studies), study design (eight studies), outcome details (six studies), and time point of drug administration (one study). Two studies from an author for whom several publications were currently retracted or listed in the retraction watch database are awaiting classification until resolution of concerns (Schietroma 2010; Schietroma 2013). Two other studies seem to share identical study arms without co-referencing each other (Isazadehfar 2016; Isazadehfar 2017). Requests for missing information were sent to all authors who reported contact email addresses in the journal publication. Requests regarding 18 studies remained unanswered.

Of the 99 study protocols retrieved in the first search, three protocols posted results on ClinicalTrials.gov (NCT00231777; NCT01149616; NCT01612702). Due to missing contact email addresses, missing information on the anaesthesia regimen or the time point of administration could not be clarified. The status of 25 studies was 'not yet recruiting' or 'recruitment' at the time of the search. The status of 71 studies was 'closed', 'completed', 'terminated', or 'unknown', and none of the protocols could be allocated to one of the included or excluded studies of the current review. Missing information for individual studies that are allocated to awaiting classification is provided under Characteristics of studies awaiting classification.

Risk of bias in included studies

The risk of bias of each included study was rated, and details on judgements are described in the Characteristics of included studies section. All judgements about each risk of bias item for each included study are graphically presented in Figure 5 (higher-resolution image is available online: Supplementary File_Summary of Risk of bias). Judgements about each risk of bias item presented as percentages across all included studies are graphically presented in Figure 6. About half of all studies were rated as low risk of bias for random sequence generation (48%), blinding of participants and personnel (46%), and blinding of outcome assessors (61%). Incomplete reporting of outcome data was a minor problem in this review, as 90% of studies have been assessed as having low risk of attrition bias. Major problems were unclear risk of selection bias due to insufficient information on allocation concealment and unclear risk of reporting bias due to lack of registered study protocols. Only 12% of all studies were assessed as having low risk of allocation concealment, and only 2% of all studies were assessed as having low risk of selective outcome reporting. The item 'other bias' captures the risk of baseline imbalance, and 12% of all studies were assessed as having low risk due to reporting on all relevant population details and prognostic variables, without any imbalance in these data.

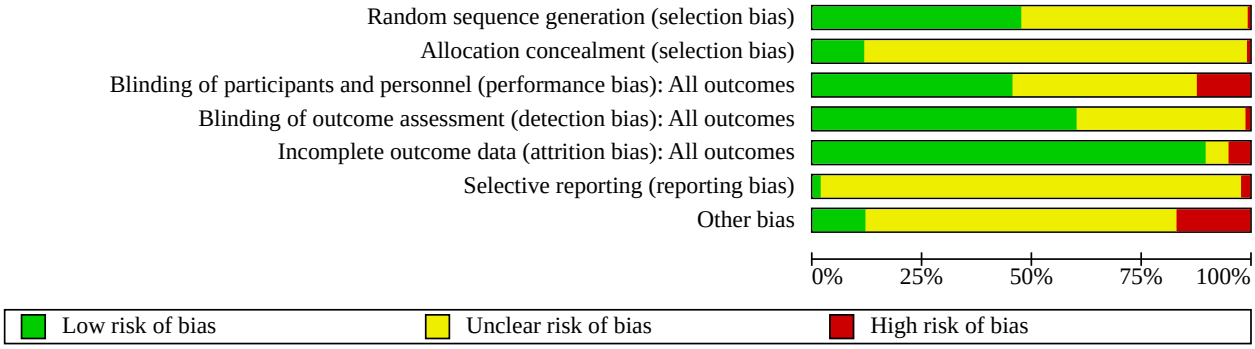
Figure 5. (Continued)

Figure 6. Risk of bias graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.



Three studies were assessed as having low risk of bias for all seven risk of bias items (NKT102245; NKT102552; Tolver 2012).

We assessed the overall risk of bias by summarizing risk of bias for the items 'sequence generation', 'blinding of participant,

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

personnel, and outcome assessors', and 'incomplete outcome data'. A total of 157 studies (27%) were assessed as having overall low risk of bias, 101 studies (17%) as having overall high risk of bias, and 327 studies (56%) as having overall unclear risk of bias.

Allocation

Random sequence generation

A total of 282 studies (48%) have reported adequate methods for sequence generation such as random number tables or computer-generated random numbers. These 282 studies were assessed as having low risk of bias. One randomized study was assessed as having high risk of selection bias according to a statement on the potential threat due to selection bias reported in the results section without further description of the study protocol (NCT00888329). All of the other 302 studies (52%) have not reported sufficient information on the method used for random sequence generation. Most often, these studies have stated only that the study was randomized without describing the method; therefore we assessed them as having unclear risk of bias.

Allocation concealment

Sixty-nine studies (12%) were judged to have low risk of bias because allocation concealment was achieved by using central allocation or sequentially numbered opaque sealed envelopes (SNOSE). Two studies were assessed as having high risk of bias (NCT00888329; Olajumoke 2013). NCT00888329 reported the risk of selection bias as a limitation in the study protocol. Olajumoke 2013 was judged as having high risk because there was a high possibility that assignments could be foreseen by using an open random allocation schedule. A total of 514 studies (88%) did not describe any method used for allocation concealment, or it was not clear from the description whether SNOSE was correctly applied to cover allocation. These studies were assessed as having unclear risk of bias.

Blinding

Blinding of participants and personnel

In 271 studies (46%), it was reported that participants and personnel were blinded. Sixty-seven studies (12%) had an unblinded study design. Most often, anaesthesiologists responsible for intraoperative management were not blinded to the treatment. In 247 studies (42%), there was no or insufficient information on blinding of participants or personnel, and statements such as 'blinded study' or 'double-blind study' were used. These studies were assessed as having unclear risk of bias.

Blinding of outcome assessment

In 355 studies (61%), it was reported that outcome assessors were blinded. Four studies (< 1%) had an unblinded study design (Dsouza 2011; Laha 2013; Lee WS 2015; Wattwil 2003). In 226 studies (39%), there was no or insufficient information on blinding of outcome assessors, and statements such as 'blinded study' or 'double-blind study' were used. These studies were assessed as having unclear risk of bias.

Incomplete outcome data

A total of 528 studies (90%) were judged as having low risk of attrition bias, 27 studies (5%) high risk, and 30 studies (5%) unclear risk.

Selective reporting

The risk of selective outcome reporting bias can be reliably assessed only if a study protocol was prospectively registered. A total of 510 studies (87%) have not published a study protocol available on the ClinicalTrials.gov or WHO ICTRP database. All of these studies were at unclear risk of reporting bias. Of the other 75 studies with registered study protocols, 58 studies have referenced the study protocol in the journal publication, six studies without a full-text journal publication have reported study results in the study protocol or the study report (NCT00888329; NKO101287; NKT102245; NKT102260; NKT102552; PALO-04-07), and 11 studies have not referenced their registered study protocols in the published journal report, and vice versa (Agarkar 2015; Alghanem 2010; Bang 2017; Blitz 2012; Choi 2016; Jung 2013; Kakuta 2011; Kim SH 2013; Kizilcik 2017; Ryoo 2015; Sanchez Rodriguez 2010). The 11 corresponding study protocols were retrieved in our search of the ClinicalTrials.gov or WHO ICTRP database, and we could allocate the protocols to the published journal reports based on corresponding study details.

Of the 75 studies (13%) with registered study protocols, 27 studies (5% of all 585 studies) were prospectively registered, 47 (8%) were retrospectively registered, and one could not be assessed due to different study dates in the protocol and in the report (Kim 2015). Of the 27 studies with prospectively registered protocols, 11 studies (2% of all 585 studies) were assessed as having low risk of selective outcme reporting bias (Altorjay 2011; Bjerregaard 2018; Gan 2011; Kranke 2012; Kranke 2013; NKO101287; NKT102245; NKT102552; PALO-04-07; Tarantino 2015; Tolver 2012), 10 studies (2%) were assessed as having high risk of selective outcome reporting bias (DeOliveira 2011; Fahlenkamp 2016; Green 2012; Hu 2017; Kim SH 2013; Sinha 2014; Soga 2015; Vallejo 2012; Yang 2017; Zhou 2012), and six studies were assessed as having unclear risk of selective outcome reporting bias (Corcoran 2017; Dewinter 2016; Kakuta 2011; Kakuta 2015; Segelman 2016; Tsutsumi 2014). All retrospectively registered studies were assessed as having unclear risk of reporting bias.

Other potential sources of bias

A total of 71 studies (12%) have had no baseline imbalance in population characteristics or risk factors for PONV between study arms and were judged as having low risk of other bias. Ninety-seven studies (17%) showed an imbalance and were judged as having high risk of other bias. In 417 studies (71%), information on relevant population characteristics or risk factors for PONV was missing, and we judged these studies as having unclear risk of other bias.

Assessment of adverse events monitoring

Sixty-one studies (10%) reported data on the outcome 'any AE'. We assessed the ways of definition and monitoring of any AE (Table 2). Eleven studies were judged as having low risk of bias because any adverse events were actively monitored (active survey) and all relevant substance class-specific AEs were included and reported (Ahn 2002; Bailey 1990; Diemunsch 2007; Gan 2007; Green 2012; Helmers 1993; Lee SY 2002; Murphy 2011a; NKT102245; NKT102260; NKT102552). Twenty-seven studies were judged as having high risk of bias because substance class-specific adverse events were not included or reported under the composite outcome AE, and there were no details on monitoring of AEs reported, or AEs were not actively monitored. Twenty-three studies provided no details on monitoring of AEs reported nor on all relevant substance class-

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

specific AEs included and reported. These studies were judged as having unclear risk of bias.

Twenty-nine studies (5%) reported data on the outcome 'SAE'. We assessed whether SAEs were defined according to an internationally accepted classification system (Table 2). Five studies defined SAEs according to the ICH guideline for good clinical practice and were assessed as having low risk of bias (Hanaoka 2004; NKT102245; NKT102260; NKT102552; Tarantino 2015). All of the other 24 studies did not define SAEs in the study report and were assessed as having high risk of bias.

Effects of interventions

See: **Summary of findings 1** Primary summary of findings; **Summary of findings 2** Summary of findings (vomiting within 24 hours postoperatively); **Summary of findings 3** Summary of findings (serious adverse events); **Summary of findings 4** Summary of findings (any adverse event); **Summary of findings 5** Summary of findings (headache); **Summary of findings 6** Summary of findings (sedation); **Summary of findings 7** Summary of findings (extrapyramidal symptoms); **Summary of findings 8** Summary of findings (constipation); **Summary of findings 9** Summary of findings (postoperative wound infection); **Summary of findings 10** Summary of findings (arrhythmia); **Summary of findings 11** Summary of findings (visual disturbances); **Summary of findings 12** Summary of findings (QT prolongation)

Summary of findings tables

Summaries of findings are presented in one primary Summary of findings (SoF) table and 11 secondary SoF tables.

The primary SoF table includes a selection of interventions according to the following criteria: single antiemetic drugs of direct interest (compared to placebo) with important beneficial effect and with high or moderate certainty of evidence for the primary outcome (vomiting) along with all relevant side effects.

- Primary SoF (Summary of findings 1)

Secondary SoF tables are outcome-specific and include all single drugs of direct interest compared to placebo.

- Vomiting (or dry retching) within 24 hours postoperatively (Summary of findings 2).
- Serious adverse events (SAEs) (Summary of findings 3).
- Any adverse event (any AE) (Summary of findings 4).
- Headache (Summary of findings 5).
- Sedation/drowsiness (Summary of findings 6).
- Extrapyramidal symptoms (Summary of findings 7).
- Constipation (Summary of findings 8).
- Postoperative wound infection (Summary of findings 9).
- Arrhythmia (Summary of findings 10).
- Visual disturbances (Summary of findings 11).
- QT prolongation (Summary of findings 12).

To get an overview about all GRADE-relevant outcomes and all single drugs of direct interest (compared to placebo), we summarized the direction of network effect estimates and the level of certainty of evidence in Figure 7 (Supplementary File_Summary of results).

Figure 7. Direction of network effect estimates (colour code) of single drugs of direct interest compared to placebo with certainty levels of evidence (high, moderate, low, very low) for all GRADE-relevant, pre-defined outcomes.

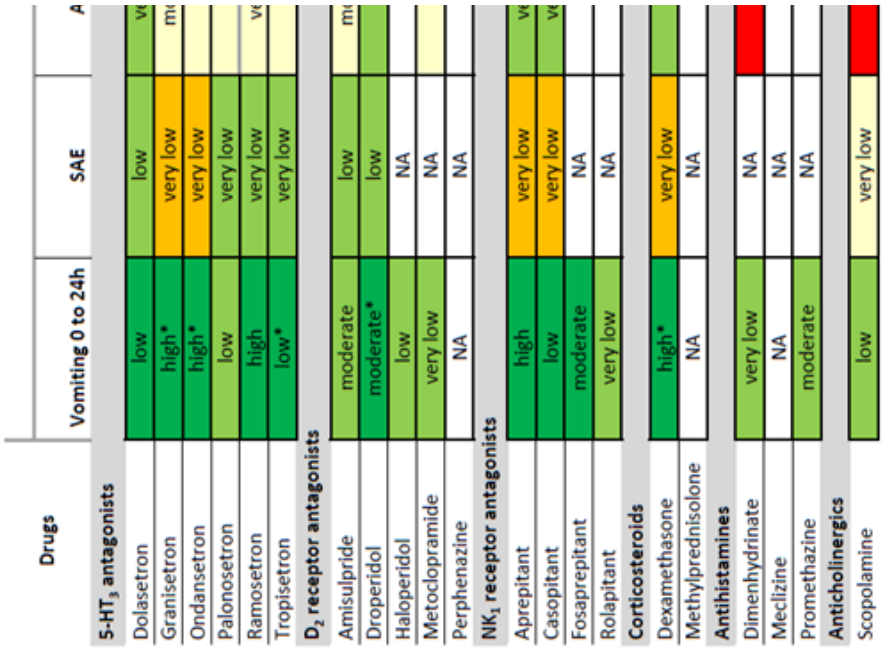
Figure 7. (Continued)



Primary outcomes

Vomiting within 24 hours postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of vomiting

Pairwise meta-analyses for vomiting comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for amisulpride (Analysis 1.1), aprepitant (Analysis 2.1), dexamethasone (Analysis 3.1), dimenhydrinate (Analysis 4.1), dolasetron (Analysis 5.1), droperidol (Analysis 6.1), granisetron (Analysis 7.1), haloperidol (Analysis 8.1), metoclopramide (Analysis 10.1), ondansetron (Analysis 11.1), palonosetron (Analysis 12.1), promethazine (Analysis 14.1), ramosetron (Analysis 15.1), rolapitant (Analysis 16.1), scopolamine (Analysis 17.1), and tropisetron (Analysis 18.1). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, not applicable (NA)).

Primary analysis of vomiting: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome vomiting (24 hours) are available in an online repository (Supplementary Files-1-vomiting 24 *; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).*

In total, 283 RCTs including 50,907 participants were eligible for the network meta-analysis of vomiting within 24 hours postoperatively. Three studies (1%) have reported zero events in all study arms. One study was not connected to the network and was excluded from the following analyses: Bergese 2016—comparison: aprepitant-dexamethasone-promethazine versus ondansetron-dexamethasone-promethazine. The network geometry of the remaining 282 studies including 50,812 participants with 572 pairwise comparisons due to multi-arm studies included 65 different treatments (nodes) (Figure 8). Of the 65 treatments, 36 were drug combinations (32 times: a two-fold combination; three times: three-fold; once: four-fold), 28 were single drugs, and one was placebo or no treatment. The most commonly studied comparisons included ondansetron (k = 77, with k = number of studies), dexamethasone (k = 43), droperidol (k = 41), metoclopramide (k = 21), and granisetron (k = 16), all compared to placebo. Of all single drugs of direct interest included in the network of vomiting, two drugs, namely, fosaprepitant (k = 3) and amisulpride (k = 2), were connected only to ondansetron and placebo, respectively.

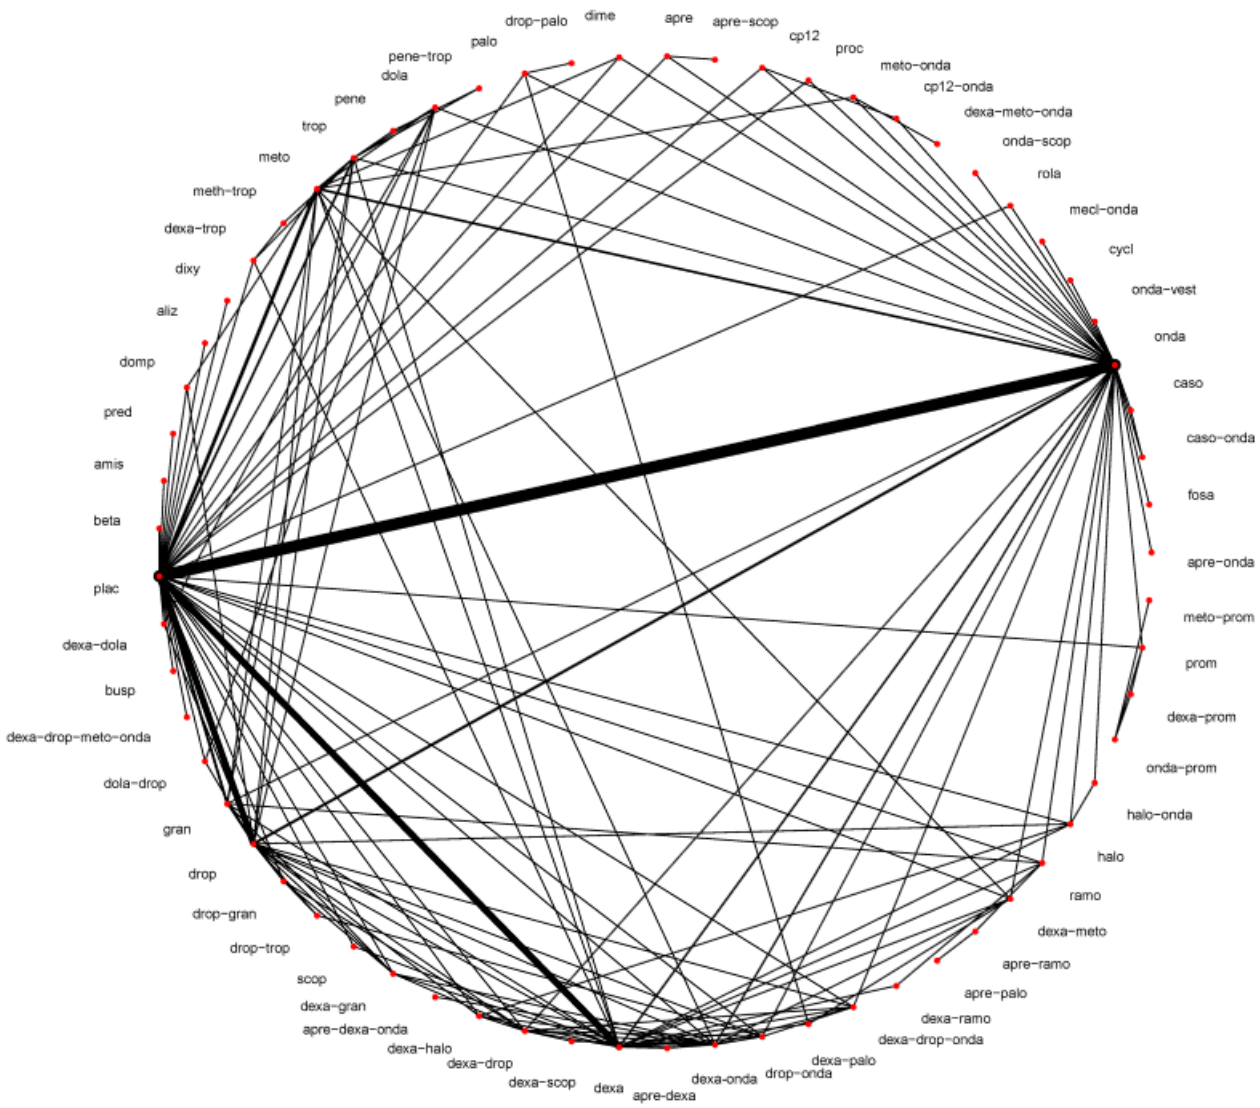
Figure 8. Network geometry of eligible comparisons for postoperative vomiting within 24 hours after surgery. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



For 65 different treatments, 2080 comparisons are possible, and the results of all network estimates are available in the online repository. For 130 of 2080 comparisons, direct and indirect evidence was available, whereas for 27 comparisons, only direct evidence was available, and for 1923 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (risk ratio (RR) with 95% confidence interval (CI)) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 9. In terms of preventing vomiting within 24 hours, 10 out of 28 single drugs showed important benefit (95% CI upper boundary < 0.8) compared to placebo, with RRs ranging between 0.06 (95% CI 0.02 to 0.21) for fosaprepitant and 0.61 (95% CI 0.54 to 0.69) for droperidol. Amongst the most effective single drugs of direct interest with important benefit for preventing vomiting compared to placebo in decreasing order according to P scores were fosaprepitant, casopitant, aprepitant, ramosetron, granisetron, dexamethasone, tropisetron, ondansetron, dolasetron, and droperidol. Fosaprepitant, the most effective drug in the network meta-analysis, was poorly connected to the network, with only three studies comparing fosaprepitant to ondansetron. Fourteen single drugs (CP-122,721, alizapride, dimenhydrinate,

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

promethazine, rolapitant, prednisolone, prochlorperazine, dixyrazine, haloperidol, scopolamine, palonosetron, amisulpride, penehyclidine, metoclopramide) showed benefit, and four drugs (cyclizine, betamethasone, domperidone, buspirone) showed no or minimal effect; all treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs compared to placebo ranged between RR 0.06 (95% CI 0.02 to 0.21) for fosaprepitant and RR 1.08 (95% CI 0.54 to 2.15) for buspirone. Of the drug combinations, 29 out of 36 drug combinations showed important benefit compared to placebo (95% CI upper boundary < 0.8), with RRs ranging between 0.01 (95% CI 0.00 to 0.19) for aprepitant-palonosetron and 0.47 (95% CI 0.28 to 0.78) for ondansetron-scopolamine. Six drug combinations showed benefit associated with uncertainty compared to placebo, and one combination (metoclopramide-promethazine) showed no or minimal effect associated with uncertainty. Treatment effects of drug combinations compared to placebo ranged between RR 0.01 (95% CI 0.00 to 0.19) for aprepitant-palonosetron and RR 1.04 (95% CI 0.17 to 6.45) for metoclopramide-promethazine.

Figure 9. Forest plot of network meta-analysis of all trials for postoperative vomiting within 24 hours after surgery. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of

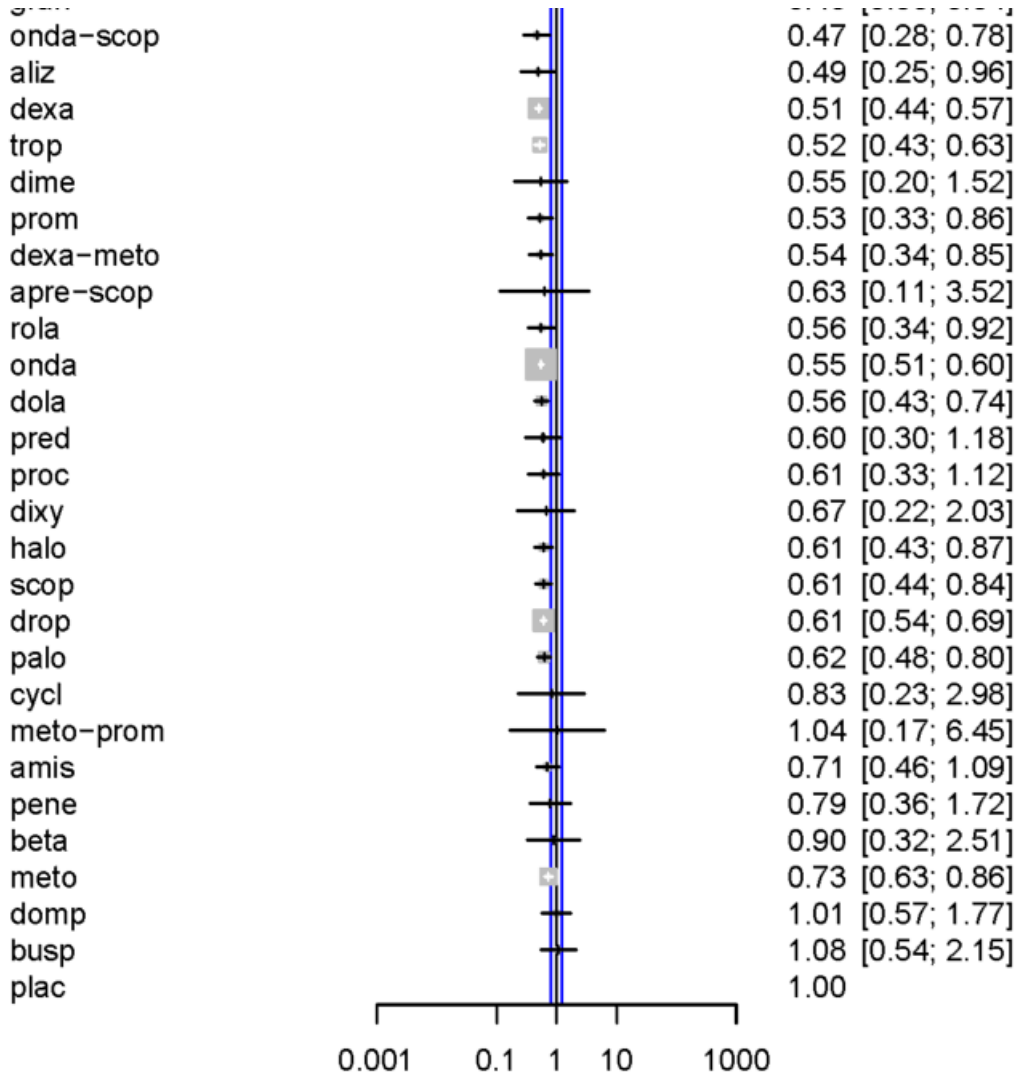
Figure 9. (Continued)



The estimated value of between-study variance for the network meta-analysis of vomiting was 0.061 (tau²) (I^2 = 45.3%). For the random-effects model, there was both large heterogeneity within designs (Q = 347.44, 179 degrees of freedom (df), P < 0.0001) and inconsistency between designs (Q = 262.98, df = 155, P < 0.0001). When the full random-effects design-by-treatment interaction model was used, there was no evidence of residual statistical inconsistency, which means that differences in treatment effects between designs are sufficient to explain all inconsistency (Q = 162.45, df = 155, P = 0.33). Clinically relevant heterogeneity for relevant comparisons (single drugs of direct interest compared to placebo) was detected for ondansetron, tropisetron, dolasetron, droperidol, amisulpride, and dexamethasone. In these cases, 95% prediction intervals (PIs) of treatment estimates included different clinical implications compared to 95% CIs. Splitting direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed disagreement (direct versus indirect) for two out of 130 comparisons, namely, dexamethasone versus ondansetron (P = 0.044) and dexamethasone-ondansetron versus placebo (P = 0.02). Clinically relevant incoherence for direct and indirect treatment estimates of single drugs of direct interest compared to placebo was found for dolasetron, haloperidol, metoclopramide, and dimenhydrinate.

Sensitivity analyses of vomiting

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of vomiting: risk of bias

For vomiting 0 to 24 hours, 44 (16%) of 282 studies were rated as high risk of overall bias, 153 (54%) studies as unclear, and 85 (30%) as low. The sensitivity network meta-analysis including only studies at low risk of bias revealed a connected network with 83 studies, excluding Dabbous 1998 (ondansetron-promethazine versus metoclopramide-

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

promethazine) and DeOliveira 2011 (metoclopramide-ondansetron versus dexamethasone-metoclopramide-ondansetron) due to lack of connection, with a total of 39 treatments including placebo. Eighteen out of 39 treatments were single drugs, with seven showing important benefit compared to placebo, including the following drugs in decreasing order according to P scores: fosaprepitant (RR 0.07, 95% CI 0.02 to 0.26); and aprepitant, ramosetron, dexamethasone, granisetron, droperidol, and ondansetron (RR 0.58, 95% CI 0.47 to 0.73). Of the single drugs of direct interest included in the primary network meta-analysis, casopitant, rolapitant, dimenhydrinate, and scopolamine were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. In contrast to the treatment effects in the primary network meta-analysis, the benefit of tropisetron (RR 0.73, 95% CI 0.38 to 1.40) and dolasetron (RR 0.46, 95% CI 0.26 to 0.82) was uncertain, and uncertainty of the benefit of palonosetron (RR 0.84, 95% CI 0.38 to 1.88) and metoclopramide (RR 0.87, 95% CI 0.58 to 1.30) was increased further. The estimated value of between-study variance for the sensitivity network meta-analysis of vomiting was 0.089 (tau^2) (I^2 = 40.3%).

Sensitivity analysis of vomiting: imbalance in baseline details and/or risk factors for PONV in study participants

We assessed studies with imbalance in baseline details and/or risk factors for PONV between study arms as having high risk of other bias. For vomiting 0 to 24 hours, 38 (13%) of 282 studies were rated as high risk of other bias, 200 (71%) studies as unclear risk of other bias, and 44 (16%) as low risk of other bias. The network graph and the forest plot of the sensitivity meta-analysis including studies at low risk of other bias are shown in the online repository with 29 treatments, including placebo. Thirteen treatments were single drugs, with five showing important benefit compared to placebo: fosaprepitant (RR 0.06, 95% CI 0.01 to 0.25); and granisetron, ramosetron, tropisetron, and ondansetron (RR 0.52, 95% CI 0.35 to 0.76). In contrast to the treatment effects of the primary network meta-analysis, the benefit of dolasetron (RR 0.44, 95% CI 0.24 to 0.83), droperidol (RR 0.56, 95% CI 0.32 to 0.97), and dexamethasone (RR 0.64, 95% CI 0.45 to 0.90) was uncertain, and uncertainty of the benefit of palonosetron (RR 0.67, 95% CI 0.31 to 1.45), metoclopramide (RR 0.53, 95% CI 0.22 to 1.28), and haloperidol (RR 0.68, 95% CI 0.28 to 1.65) was increased further. Amisulpride, aprepitant, casopitant, dimenhydrinate, promethazine, and scopolamine were not included in the sensitivity network meta-analysis due to lack of studies with low risk of other bias. The estimated value of between-study variance for this sensitivity network meta-analysis of vomiting was 0.113 (tau^2) (I^2 = 44.1%).

Sensitivity analysis of vomiting: studies with PONV-related primary outcome(s)

In total, 150 (54%) of 282 studies have defined a PONV-related primary outcome in their published study report. The network of this sensitivity analysis consisted of 53 treatments including placebo, with 23 single-drug treatments. Ten single drugs compared to placebo showed important benefits in this sensitivity analysis, which were robust compared to those of the primary analysis. Promethazine was not included in the sensitivity analysis. The estimated value of between-study variance for this sensitivity network meta-analysis of vomiting was 0.0295 (tau^2) (I^2 = 36.8%).

Sensitivity analysis of vomiting: funding source

Fifty-five (20%) of 282 studies were reported to be funded by industry sources, 46 (16%) studies were funded by non-industrial resources, and 181 (64%) studies provided no information on funding source. Two sensitivity analyses—one for industry-funded and one for non-industry-funded studies—were performed. The network of the sensitivity analysis including only industry-funded studies consisted of 32 treatments including 17 single drugs and placebo. Compared to the primary analysis, treatment effects for five out of 17 single drugs (granisetron, droperidol, dolasetron, dexamethasone, metoclopramide) were not robust. Granisetron (RR 0.57, 95% CI 0.34 to 0.94), droperidol (RR 0.64, 95% CI 0.48 to 0.86), dolasetron (RR 0.66, 95% CI 0.38 to 1.13), and dexamethasone (RR 0.73, 95% CI 0.53 to 0.99) showed benefit associated with uncertainty compared to placebo. Metoclopramide (RR 1.06, 95% CI 0.62 to 1.81) showed no or minimal effect associated with uncertainty compared to placebo. The network of the sensitivity analysis including only non-industry-funded studies consisted of 25 treatments including 13 single drugs and placebo. Compared to the primary analysis, treatment effects of eight out of 13 single drugs (promethazine, palonosetron, tropisetron, dolasetron, granisetron, aprepitant, droperidol, ramosetron) in the sensitivity analysis were not robust. Promethazine (RR 0.26, 95% CI 0.09 to 0.78) and palonosetron (RR 0.37, 95% CI 0.19 to 0.72) showed important benefit compared to placebo. Tropisetron (RR 0.52, 95% CI 0.21 to 1.29), dolasetron (RR 0.54, 95% CI 0.32 to 0.88), granisetron (RR 0.56, 95% CI 0.34 to 0.93), aprepitant (RR 0.59, 95% CI 0.23 to 1.55) and droperidol (RR 0.66, 95% CI 0.51 to 0.85) showed benefit associated with uncertainty compared to placebo. Ramosetron (RR 0.81, 95% CI 0.36 to 1.83) showed no or minimal effect associated with uncertainty compared to placebo.

Casopitant, scopolamine, rolapitant, and amisulpride were represented only in the sensitivity analysis including industry-funded studies, and fosaprepitant, promethazine, haloperidol, and ramosetron only in the sensitivity analysis including non-industry-funded studies, respectively. Nine single drugs were included in both sensitivity analyses, with no differences in treatment effects for granisetron, ondansetron, dolasetron, and droperidol; more favourable results for aprepitant and tropisetron in industry-funded studies; and more favourable results for dexamethasone, palonosetron, and metoclopramide in non-industry-funded studies. For studies investigating dimenhydrinate, the funding source was not specified.

Reporting bias (vomiting)

Ten direct pair-wise comparisons included 10 or more studies for which small-study effects such as reporting or publication bias were investigated: ondansetron, dexamethasone, droperidol, metoclopramide, granisetron, and tropisetron were compared to placebo; and droperidol, metoclopramide, dexamethasone, and dexamethasone-ondansetron were compared to ondansetron. For all comparisons, funnel plots with interpretation, results of the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. According to explorative analyses, we suspected publication bias for the comparisons droperidol versus placebo (P = 0.005) and metoclopramide versus ondansetron (P = 0.01). Small P values when the arcsine test was used to detect funnel plot asymmetry were also found for ondansetron versus placebo (P = 0.01), dexamethasone versus placebo (P =0.0164), and dexamethasone

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

versus ondansetron (P = 0.06). Contour-enhanced funnel plots suggested asymmetry for dexamethasone, granisetron, and ondansetron versus placebo. However, we did not suspect relevant publication bias for these comparisons because trim and fill sensitivity analysis did not change the conclusion with respect to the range of equivalence. Asymmetry may have been due to other factors such as heterogeneity (see "Certainty of evidence: vomiting").

Subgroup analysis of vomiting: dose effects

To account for the treatment effect modifier dose, we performed a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. We restricted splitting of doses to single drugs.

First, we conducted a network meta-analysis including single drugs only (and excluding combination treatments) with 230 RCTs and 29 treatments including placebo. The network was well connected, and effect estimates as well as the ranking order of drugs with placebo as comparator were comparable to the primary analysis, including combination prophylaxis. The estimated value of between-study variance for the network meta-analysis of single drugs for vomiting was 0.061 (tau^2) (I^2 = 48.3%).

Second, we conducted the subgroup analysis on dose for the network of single drugs only. We split the following drugs into dose categories: amisulpride, aprepitant, dexamethasone, dolasetron, droperidol, granisetron, haloperidol, ondansetron, palonosetron, promethazine, ramosetron, rolapitant, and tropisetron. For casopitant, dimenhydrinate, and metoclopramide, only one dose category (low, recommended, or high) was available for the subgroup analysis. Drugs without any dose recommendation according to Table 1 (fosaprepitant, scopolamine) and drugs not of direct interest (alizapride, betamethasone, buspirone, CP-122,721, cyclizine, dixyrazine, domperidone, penehyclidine, prednisolone, prochlorperazine) were included in the analysis and were lumped together, irrespective of the doses being analysed, in a category labelled 'NA'. We excluded six studies from the subgroup analysis because they were not attributable to one of the three dose categories (Eberhart 2006; Heidari 2015b; Huseyinoglu 2016; Jakobsson 1999; Phillips 1993; Verhasselt 1988). We split the subgroup network meta-analysis with 224 studies and 29 treatments including placebo into 50 nodes with dose categories, and this is presented in the online repository. In ranking of drugs according to efficacy with placebo as the comparator for higher or recommended doses of drugs ranked higher than lower doses, however, most of the 95% CIs were overlapping between different dose categories of the same drug. For dexamethasone, droperidol, granisetron, ondansetron, rolapitant, and tropisetron, the 95% CIs of the low doses showed uncertain benefit in contrast to recommended and/or high doses of the same drug.

We have summarized the most commonly used dosages, routes, and time points of administration of single drugs of direct interest for the primary outcome vomiting in Table 3.

Additivity of dose categories (vomiting)

A network meta-analysis with the assumption of additivity of dose categories revealed similar results as the standard network meta-analysis model when point estimates and 95% CIs were compared, suggesting additive dose effects. However, the Q-statistic of the difference between standard and additive network meta-analyses for vomiting suggests that the standard model explained the data better than the additive model (P = 0.03). This may be due to the fact that, for all drugs, the categories high and recommended for the same drug showed similar effect estimates, which generally were more effective than the corresponding low dose categories.

Sensitivity analysis of vomiting: comparability of doses between study arms

In 137 (60%) of 230 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis consisted of 15 treatments including placebo. Rolapitant and dimenhydrinate were not included in the sensitivity analysis due to lack of studies with comparable doses between intervention and control arms. Eight single drugs showed important benefit compared to placebo, including casopitant (RR 0.14, 95% CI 0.06 to 0.32); and promethazine, dexamethasone, ramosetron, tropisetron, granisetron, ondansetron, and droperidol (RR 0.60, 95% CI 0.52 to 0.70). Treatment effects were comparable to the primary network meta-analysis with all single drugs, except for promethazine, which showed important benefit in the sensitivity analysis; and for two drugs, aprepitant (RR 0.59, 95% CI 0.23 to 1.55) and dolasetron (RR 0.63, 95% CI 0.45 to 0.87), which showed uncertain benefit compared to placebo. The estimated value of between-study variance for this sensitivity network meta-analysis of vomiting was 0.060 (tau^2) (I^2 = 54.7%).

Additive effects of combinations of treatments (vomiting)

We tested the hypothesis of additivity of the components in combination prophylaxis by comparing the primary standard analysis (k = 282) with a second analysis, which assumes that the effects of combined treatments are additive sums of their components. This assumption is very strong and general, as the analysis assumes additive effects for all components included in the analysis. The Q-statistic of the difference between standard and additive network meta-analyses for vomiting suggests that the standard model explained the data better than the additive model (P = 0.006). On the level of individual comparisons, the additive model shrunk the effects compared to the standard model for aprepitant-palonosetron, aprepitant-ramosetron, dexamethasone-dolasetron, dexamethasone-metoclopramide-ondansetron, dexamethasone-ramosetron, haloperidol-ondansetron, metoclopramide-ondansetron, and penehyclidine-tropisetron. In these cases, effects in the standard model are larger (smaller RR) than expected under the additivity assumption, which may indicate positive interaction of the components. In contrast, the additive model enlarged effects compared to the standard model for aprepitant-dexamethasone-ondansetron, aprepitant-scopolamine, dexamethasone-metoclopramide, dexamethasone-promethazine, and metoclopramide-promethazine. In these cases, effects in the standard model are smaller (larger RR) than expected under the additivity assumption, which may indicate negative interaction of the components. For all other combinations of treatments, especially the combinations used most frequently (dexamethasone-ondansetron, droperidol-ondansetron, dexamethasone-granisetron), effects of standard and additive models were comparable, suggesting additive effects of the single components.

Certainty of evidence: vomiting

The certainty of evidence of treatment estimates for vomiting evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 2).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for vomiting 0 to 24 hours ranged from low to high (Summary of findings 2). Ramosetron (RR 0.44, 95% CI 0.32 to 0.59) reduces vomiting compared to placebo with high-certainty evidence. The certainty of evidence for ondansetron (RR 0.55, 95% CI 0.51 to 0.60) and granisetron (RR 0.45, 95% CI 0.38 to 0.54), which also reduce vomiting compared to placebo, was also rated as high. However, high certainty of evidence applies to recommended and high doses of ondansetron and granisetron because low doses showed no clinically important benefit. Tropisetron (RR 0.52, 95% CI 0.43 to 0.63) and dolasetron (RR 0.56, 95% CI 0.43 to 0.74) may reduce vomiting compared to placebo, with low-certainty evidence for tropisetron (serious concerns for study limitation) and dolasetron (study limitation, heterogeneity-incoherence). Low certainty of evidence for tropisetron is restricted to recommended and high doses. Palonosetron (RR 0.62, 95% CI 0.48 to 0.80) may reduce vomiting, for which the certainty of evidence is low (study limitation, imprecision).

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for vomiting 0 to 24 hours ranged from very low to moderate (Summary of findings 2). Droperidol (RR 0.61, 95% CI 0.54 to 0.69) probably reduces vomiting, with moderate-certainty evidence (publication bias-heterogeneity). However, moderate certainty of evidence applies to recommended and high doses of droperidol. Amisulpride (RR 0.71, 95% CI 0.46 to 1.09), with direct evidence only, probably reduces vomiting, with moderate-certainty evidence (imprecision-heterogeneity). Haloperidol (RR 0.61, 95% CI 0.43 to 0.87) may reduce vomiting, with low-certainty evidence (imprecision, incoherence). We are uncertain whether metoclopramide (RR 0.73, 95% CI 0.63 to 0.86) reduces vomiting due to very low-certainty evidence (study limitation, imprecision, incoherence). No studies reporting vomiting were available for perphenazine.

For relevant NK_1 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for vomiting 0 to 24 hours ranged from very low to high (Summary of findings 2). Fosaprepitant (RR 0.06, 95% CI 0.02 to 0.21), casopitant (RR 0.16, 95% CI 0.07 to 0.35), and aprepitant (RR 0.26, 95% CI 0.18 to 0.38) were the most effective drugs for vomiting compared to placebo in the current network meta-analysis. Aprepitant reduces vomiting, with high-certainty evidence. Fosaprepitant, with indirect evidence only, probably reduces vomiting, with moderate-certainty evidence (incoherence). Casopitant, also with indirect evidence only, may reduce vomiting, with low-certainty evidence (study limitation, incoherence). We are uncertain whether rolapitant (RR 0.56, 95% CI 0.34 to 0.92) reduces vomiting, as the certainty of evidence was very low (serious concerns for study limitation, imprecision).

The only reported corticosteroid was dexamethasone (RR 0.51, 95% CI 0.44 to 0.57), which reduces vomiting, with high-certainty evidence (Summary of findings 2). However, high certainty of evidence applies to recommended and high doses of dexamethasone. No studies reporting vomiting were available for methylprednisolone.

For relevant antihistamines (compared to placebo), the certainty of evidence of network effect estimates for vomiting 0 to 24 hours was moderate and very low (Summary of findings 2). Promethazine (RR 0.53, 95% CI 0.33 to 0.86) probably reduces vomiting, with moderate-certainty evidence (imprecision). We are uncertain whether dimenhydrinate (RR 0.55, 95% CI 0.20 to 1.52) reduces vomiting, as certainty of evidence was very low (study limitation, incoherence, very serious concerns for imprecision). No studies reporting vomiting were available for meclizine.

The anticholinergic scopolamine (RR 0.61, 95% CI 0.44 to 0.84) may reduce vomiting, with low-certainty evidence (study limitation, imprecision) (Summary of findings 2).

SAEs within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of SAEs

Pairwise meta-analyses for SAEs comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for amisulpride (Analysis 1.2), dexamethasone (Analysis 3.2), dolasetron (Analysis 5.2), droperidol (Analysis 6.2), granisetron (Analysis 7.2), ondansetron (Analysis 11.2), palonosetron (Analysis 12.2), ramosetron (Analysis 15.2), scopolamine (Analysis 17.2), and tropisetron (Analysis 18.2). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

Primary analysis of SAEs: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome SAEs are available in an online repository (Supplementary Files-2-SAE *; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).*

Twenty-nine studies with 10,886 participants were eligible for the network meta-analysis of SAEs. Twelve studies (41%) have reported zero events in all study arms. One study was not connected to the network and was excluded from the following analysis: Papadimitriou 2001; comparison: metoclopramide-tropisetron versus metoclopramide. The network of the remaining 28 studies with 52 pair-wise comparisons due to multi-arm studies included 22 treatments (nodes), of which placebo (k = 26) and ondansetron (k = 14) were the most frequent comparators (Figure 10). Of the 22 treatments, eight were two-fold drug combinations, 13 were single drugs, and one was placebo or no treatment. The most common comparisons with three studies each were between ondansetron versus placebo, dexamethasone versus placebo, dolasetron versus placebo, palonosetron versus placebo, and casopitant-ondansetron versus ondansetron. Of all single drugs of direct interest included in the network of SAEs, amisulpride, dolasetron, palonosetron, and scopolamine were connected only to placebo, and aprepitant was connected only to ondansetron.

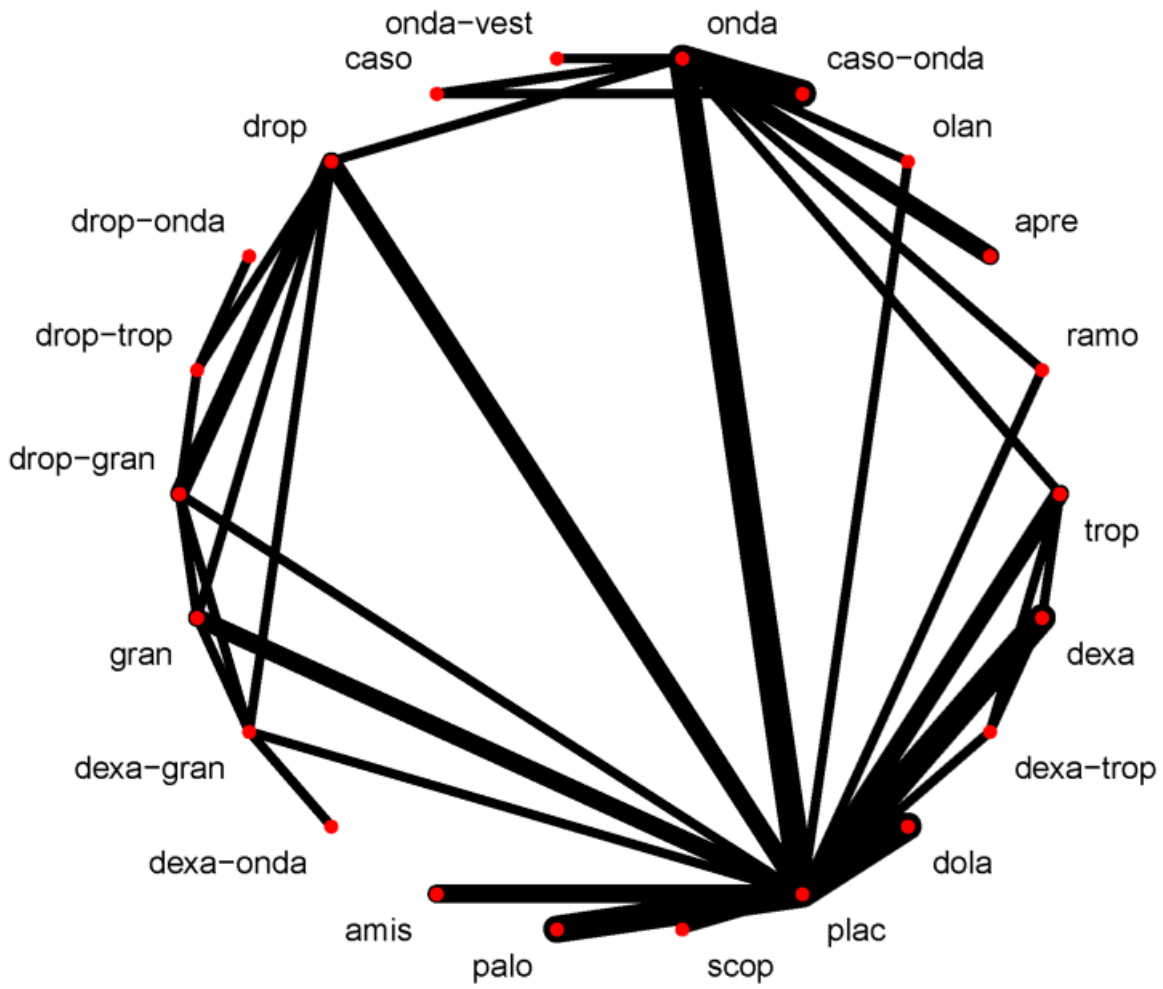
Figure 10. Network geometry of eligible comparisons for serious adverse events (SAE) within 7 days postoperatively. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



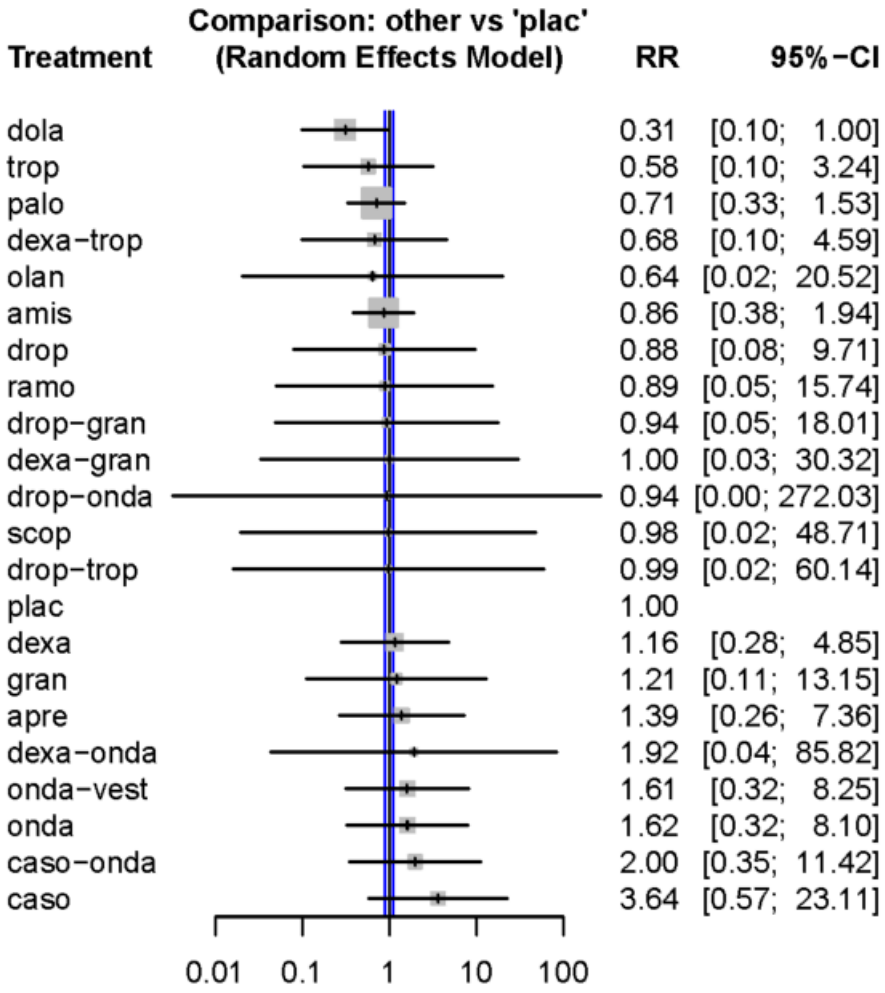
For 22 different treatments, 231 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 27 of 231 comparisons, direct and indirect evidence was available, whereas for nine comparisons, only direct evidence was available, and for 195 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (RR with 95% CIs) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 11. In terms of reducing the number of participants with SAEs, none of the 21 treatments showed important benefit (95% CI upper boundary < 0.9) or important harm (95% CI lower boundary > 1.11) compared to placebo. Of the 13 single drugs compared to placebo, seven showed benefit (dolasetron, tropisetron, palonosetron, olanzapine, amisulpride, droperidol, ramosetron), one showed no or minimal effect (scopolamine), five showed harm (dexamethasone, granisetron, aprepitant, ondansetron, casopitant), and all 13 treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs compared to placebo ranged between RR 0.31 (95% CI 0.10 to 1.00) for dolasetron and 3.64 (95%

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

CI 0.57 to 23.11) for casopitant. Of the eight combination treatments, one showed benefit (dexamethasone-tropisetron), four showed no or minimal effect (droperidol-granisetron, dexamethasone-granisetron, droperidol-ondansetron, droperidol-tropisetron), three showed harm (dexamethasone-ondansetron, ondansetron-vestipitant, casopitant-ondansetron), and all eight treatment effects were associated with uncertainty. Treatment effects of drug combinations compared to placebo ranged between RR 0.68 (95% CI 0.10 to 4.59) for dexamethasone-tropisetron and RR 2.00 (95% CI 0.35 to 11.42) for casopitant-ondansetron.

Figure 11. Forest plot of network meta-analysis of all trials for serious adverse events (SAE) within 7 days postoperatively. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to 1.11). Treatments are ranked according to safety based on P scores. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



The estimated value of between-study variance for the network meta-analysis of SAEs was 0 (tau^2) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 3.66, df = 8, P = 0.89) and no inconsistency between designs (Q = 4.49, df = 9, P = 0.88). No clinically relevant heterogeneity for relevant comparisons (single drugs of direct interest compared to placebo) was detectable because 95% CIs and 95% PIs were compatible with respect to the range of equivalence. Splitting of direct and

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

indirect evidence in the network meta-analysis and testing for local inconsistency revealed no relevant disagreement (direct versus indirect) for any of the 27 comparisons. There was no clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo.

Sensitivity analyses of SAEs

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of SAEs: risk of bias

Three (11%) of 28 studies were rated as having high risk of overall bias, 14 (50%) as unclear, and 11 (39%) as low. The sensitivity network meta-analysis including only studies at low risk of bias revealed a poorly connected network, with 11 treatments and 11 studies. Three treatments were two-fold combinations of antiemetic drugs, seven treatments were single drugs, and one was placebo or no treatment. Of the single drugs of direct interest, granisetron, tropisetron, ramosetron, dolasetron, and scopolamine were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Effect estimates of five single drugs (aprepitant, ondansetron, casopitant, dexamethasone, palonosetron) compared to placebo in this sensitivity analysis were not robust when compared to the primary network meta-analysis. Aprepitant, ondansetron, and casopitant with RR 0.23 (95% CI 0.00 to 11.55), RR 0.26 (95% CI 0.01 to 13.12), and RR 0.59 (95% CI 0.01 to 32.74), respectively, showed benefit associated with uncertainty. Dexamethasone and palonosetron showed no or minimal effects, with RR 1.00 (95% CI 0.02 to 49.75) and RR 1.00 (95% CI 0.02 to 49.43), respectively—both associated with uncertainty. The estimated value of between-study variance for the sensitivity network meta-analysis of SAEs was 0 (tau^2) (I^2 = 0%).

Sensitivity analysis of SAEs: risk of bias for monitoring and reporting of SAEs

In a sensitivity network meta-analysis for monitoring and reporting of SAEs, we included only studies that have defined SAEs in the study report according to an accepted international classification system. Only five (18%) of 28 studies were assessed as having low risk of bias for monitoring and reporting of SAEs. The five studies were not connected. Two studies compared either granisetron—Hanaoka 2004—or dexamethasone—Tarantino 2015—to placebo, and three studies from GlaxoSmithKline compared casopitant-ondansetron or casopitant to ondansetron (NKT102245; NKT102260; NKT102552). Compared to the primary analysis, the treatment effect for dexamethasone versus placebo was not robust and showed no or minimal effect associated with uncertainty (RR 1.00, 95% CI 0.02 to 49.75). Casopitant showed harm associated with uncertainty compared to ondansetron (RR 2.25, 95% CI 0.91 to 5.58).

Sensitivity analysis of SAEs: imbalance in baseline details and/or risk factors for PONV in study participants

We assessed studies with an imbalance in baseline details and/or risk factors for PONV between the study arms as having high risk of other bias. For SAEs, three (11%) of 28 studies were rated as high risk of other bias, 18 (64%) as unclear, and seven (25%) as low. The seven studies with low risk of other bias were not connected in one network. Four of these studies with 10 treatments including placebo as comparator were connected in one sub-network. Three other studies from GlaxoSmithKline with ondansetron as comparator were included in the other sub-network (NKT102245; NKT102260; NKT102552). Of the single drugs, dolasetron, aprepitant, scopolamine, and amisulpride were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Compared to the primary analysis, treatment effects for palonosetron, granisetron, droperidol, dexamethasone, all compared to placebo, were not robust and showed no or minimal effect associated with uncertainty.

Sensitivity analysis of SAEs: studies with PONV-related primary outcome(s)

Twenty-two (79%) of 28 studies have defined a PONV-related primary outcome in their published study report. The network of this sensitivity analysis consisted of 18 treatments including placebo (six combination and 11 single drug treatments). Of the single drugs, ramosetron and scopolamine were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. The relative treatment effects of all single drugs compared to placebo were comparable to the primary analysis, with RRs ranging between 0.31 (95% CI 0.10 to 1.00) for dolasetron and 4.07 (95% CI 0.60 to 27.64) for casopitant. The estimated value of between-study variance for this sensitivity network meta-analysis of SAE was 0 (tau^2) (I^2 = 0%).

Sensitivity analysis of SAEs: funding source

Seventeen (61%) of 28 studies were funded by industry, six (21%) were funded by non-industrial resources, and for another five studies (18%), information on funding source was not provided. Two sensitivity analyses—one for industry-funded and one for non-industry-funded studies—were performed. The network of the sensitivity analysis including only industry-funded studies consisted of 16 studies with 12 treatments, including nine single drugs and placebo. One study was not connected to the network and was excluded from the analyses (Gan 2005; comparison: dexamethasone-granisetron versus dexamethasone-ondansetron). Compared to the primary analysis, of the nine single drugs, treatment effects of casopitant and tropisetron compared to placebo were not robust. Casopitant (RR 38.81, 95% CI 1.95 to 770.47) showed important harm compared to placebo. However, only indirect evidence was available because casopitant was connected only to ondansetron. Tropisetron (RR 6.50, 95% CI 0.34 to 125.35) showed harm associated with uncertainty compared to placebo. The network of the sensitivity analysis including only studies funded by non-industrial resources consisted of six studies with three combinations, six single drugs, and placebo. Compared to the primary analysis, of the six single drugs, treatment effects of ondansetron, granisetron, dexamethasone, and palonosetron were not robust. Ondansetron (RR 0.38, 0.01 to 14.33) and granisetron (RR 0.70, 0.02 to 26.19) compared to placebo showed benefit, and both dexamethasone (RR 1.00, 95% CI 0.02 to 49.75) and palonosetron (RR 1.00, 95% CI 0.02 to 49.43) showed no or minimal effect compared to placebo; all effects were associated with uncertainty.

Six single drugs were funded only by industry (dolasetron, amisulpride, scopolamine, tropisetron, aprepitant, casopitant), and three solely by non-industrial resources (ramosetron, droperidol, dexamethasone). Three single drugs (ondansetron, granisetron, and palonosetron) were investigated in studies funded

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

by either of the sources, and treatment effects were not robust in either analysis. Ondansetron and granisetron showed results that were more favourable in non-industry-funded studies than in industry-funded studies. Palonosetron showed results that were more favourable in industry-funded studies than in non-industry-funded studies. The comparison of results from both sensitivity analyses is associated with high uncertainty and should be viewed with caution due to the small number of included studies.

Reporting bias (SAE)

None of the direct pair-wise comparisons included 10 or more studies. Therefore, analyses investigating reporting or publication bias were not performed.

Subgroup analysis of SAEs: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis including single drugs only (and excluding combination treatments) with 22 studies and 14 treatments including placebo was conducted. Network geometry, effect estimates, and the ranking order of drugs with placebo as comparator were comparable to the primary analysis, including combination prophylaxis. The estimated value of between-study variance for the network meta-analysis of single drugs for SAEs was 0 (tau^2) (I^2 = 0%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. The following drugs were split into dose categories: amisulpride, aprepitant, dolasetron, ondansetron, palonosetron, and ramosetron. For casopitant, dexamethasone, droperidol, granisetron, and tropisetron, only one dose category was available for subgroup analysis. Drugs without any dose recommendation according to Table 1 (scopolamine) and drugs not of direct interest (olanzapine) were included in the analysis and were lumped together, irrespective of the doses being analysed, in the category 'NA'. Three studies—Diemunsch 1998; Eberhart 2006; Warriner 1997—and one arm of Lee 2008a (0.1 mg oral ramosetron) were excluded from the subgroup analysis because they were not associated with one of the three dose categories. The network was poorly connected, with 19 studies and 14 treatments split into 21 nodes with dose categories. Ranking of drugs according to safety with placebo as comparator is presented in the online repository. All available dose categories for dolasetron and palonosetron compared to placebo showed benefit associated with uncertainty. For aprepitant, all dose categories compared to placebo showed harm associated with uncertainty. Amisulpride used as recommended or low doses showed benefit, high doses showed harm, and all treatment effects were associated with uncertainty. Low doses of ramosetron showed no or minimal effect and recommended doses showed harm, and both treatment effects were associated with uncertainty. Recommended doses of ondansetron showed harm, high doses showed benefit, and both treatment effects were associated with high uncertainty. Recommended doses of casopitant (RR 42.47, 95% CI 1.98 to 910.14) showed important harm. However, evidence for these results was restricted to only one study directly comparing recommended doses of casopitant and ondansetron. Casopitant was not otherwise connected in the network.

Additivity of dose categories (SAEs)

A network meta-analysis with the assumption of additivity of the dose categories revealed no difference between standard and additive models (P = 0.34), suggesting additive dose effects. The analysis was based on a few studies that currently make reliable statements on additive effects of drug doses impossible.

Sensitivity analysis of SAEs: comparability of doses

In 13 (46%) of 28 studies investigating single drugs, comparable doses of the antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that could be assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis was poorly connected, consisting of 11 treatments including placebo, which limited evidence. Aprepitant and scopolamine were not included in the sensitivity analysis due to lack of studies with comparable doses. Effect estimates of five single drugs (casopitant, droperidol, tropisetron, ramosetron, dexamethasone) compared to placebo in this sensitivity analysis were not robust when compared to the network meta-analysis including single drugs only. Casopitant (RR 42.47, 95% CI 1.98 to 910.14) showed important harm. Droperidol, tropisetron, and ramosetron, with RR 1.14 (95% CI 0.03 to 41.28), RR 6.50 (95% CI 0.34 to 125.35), and RR 17.25 (95% CI 0.14 to 2135.86), respectively, showed harm associated with high uncertainty. Dexamethasone showed no or minimal effect, with RR 1.01 (95% CI 0.06 to 15.98) associated with uncertainty. The estimated value of between-study variance for this sensitivity network meta-analysis of SAEs was 0 (tau^2) (I^2 = 0%).

Additive effects of combinations of treatments (SAEs)

We tested the hypothesis of additivity of the components in combination prophylaxis by comparing the primary standard analysis (k = 28) with a second analysis, which assumes that the effects of combined treatments are additive sums of their components. We detected no differences between standard and additive models (P = 0.89), suggesting additive dose effects. However, the analysis was based on only a few studies that currently make reliable statements on additive effects of drug combinations impossible.

Certainty of evidence: SAEs

Certainty of evidence of treatment estimates for the outcome SAEs evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 3).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for the outcome SAEs ranged from very low to low (Summary of findings 3). Dolasetron (RR 0.31, 95% CI 0.10 to 1.00), with direct evidence only, may reduce the number of participants with SAEs compared to placebo, with low-certainty evidence (study limitations, imprecision). The certainty of evidence for all other 5-HT_3 receptor antagonists was assessed as very low. We are uncertain whether ondansetron (RR 1.62, 95% CI 0.32 to 8.10) and granisetron (RR 1.21, 95% CI 0.11 to 13.15) compared to placebo increase the number of participants with SAEs, with very low-certainty evidence (study limitations, very serious concerns for imprecision). We are uncertain whether tropisetron (RR 0.58, 95% CI 0.10 to 3.24) and palonosetron (RR 0.71, 95% CI 0.33 to

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

1.53) compared to placebo decrease the number of participants with SAEs, with very low-certainty evidence (study limitations, very serious concerns for imprecision). We are uncertain whether ramosetron (RR 0.89, 95% CI 0.05 to 15.74) compared to placebo decreases the number of participants with SAEs, with very low-certainty evidence (very serious concerns for study limitations and imprecision). For palonosetron, only direct evidence was available.

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for SAEs was assessed as low (Summary of findings 3). Droperidol (RR 0.88, 95% CI 0.08 to 9.71) and amisulpride (RR 0.86, 95% CI 0.38 to 1.94) may reduce the number of participants with SAEs compared to placebo, with low-certainty evidence (very serious concerns for imprecision). For amisulpride, only direct evidence was available. No studies reporting SAEs were available for metoclopramide, haloperidol, or perphenazine.

For relevant NK_1 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for SAEs was assessed as very low (Summary of findings 3). We are uncertain whether casopitant (RR 3.64, 95% CI 0.57 to 23.11) and aprepitant (RR 1.39, 95% CI 0.26 to 7.36), both with indirect evidence only, increase the number of participants with SAEs compared to placebo, with very low-certainty evidence (study limitation, incoherence, very serious concerns for imprecision). No studies reporting SAEs were available for fosaprepitant and rolapitant.

The only corticosteroid that was included in the network meta-analysis for SAEs was dexamethasone, with very low-certainty evidence. We are uncertain whether dexamethasone (RR 1.16, 95% CI 0.28 to 4.85) increases the number of participants with SAEs compared to placebo (study limitations, very serious concerns for imprecision) (Summary of findings 3). No studies reporting SAEs were available for methylprednisolone.

No studies reporting SAEs were available for relevant antihistamines (compared to placebo) (Summary of findings 3).

For the anticholinergic scopolamine, with only direct evidence, the certainty of evidence was considered as very low (very serious concerns for study limitations and imprecision) (Summary of findings 3). We are uncertain whether scopolamine (RR 0.98, 95% CI 0.02 to 48.71) compared to placebo has no or minimal effects on SAEs.

Any AE within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of any AE

Pairwise meta-analyses of any AE comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for amisulpride (Analysis 1.3), dexamethasone (Analysis 3.3), dolasetron (Analysis 5.3), droperidol (Analysis 6.3), granisetron (Analysis 7.3), metoclopramide (Analysis 10.2), ondansetron (Analysis 11.3), palonosetron (Analysis 12.3), ramosetron (Analysis 15.3), scopolamine (Analysis 17.3), and tropisetron (Analysis 18.3). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

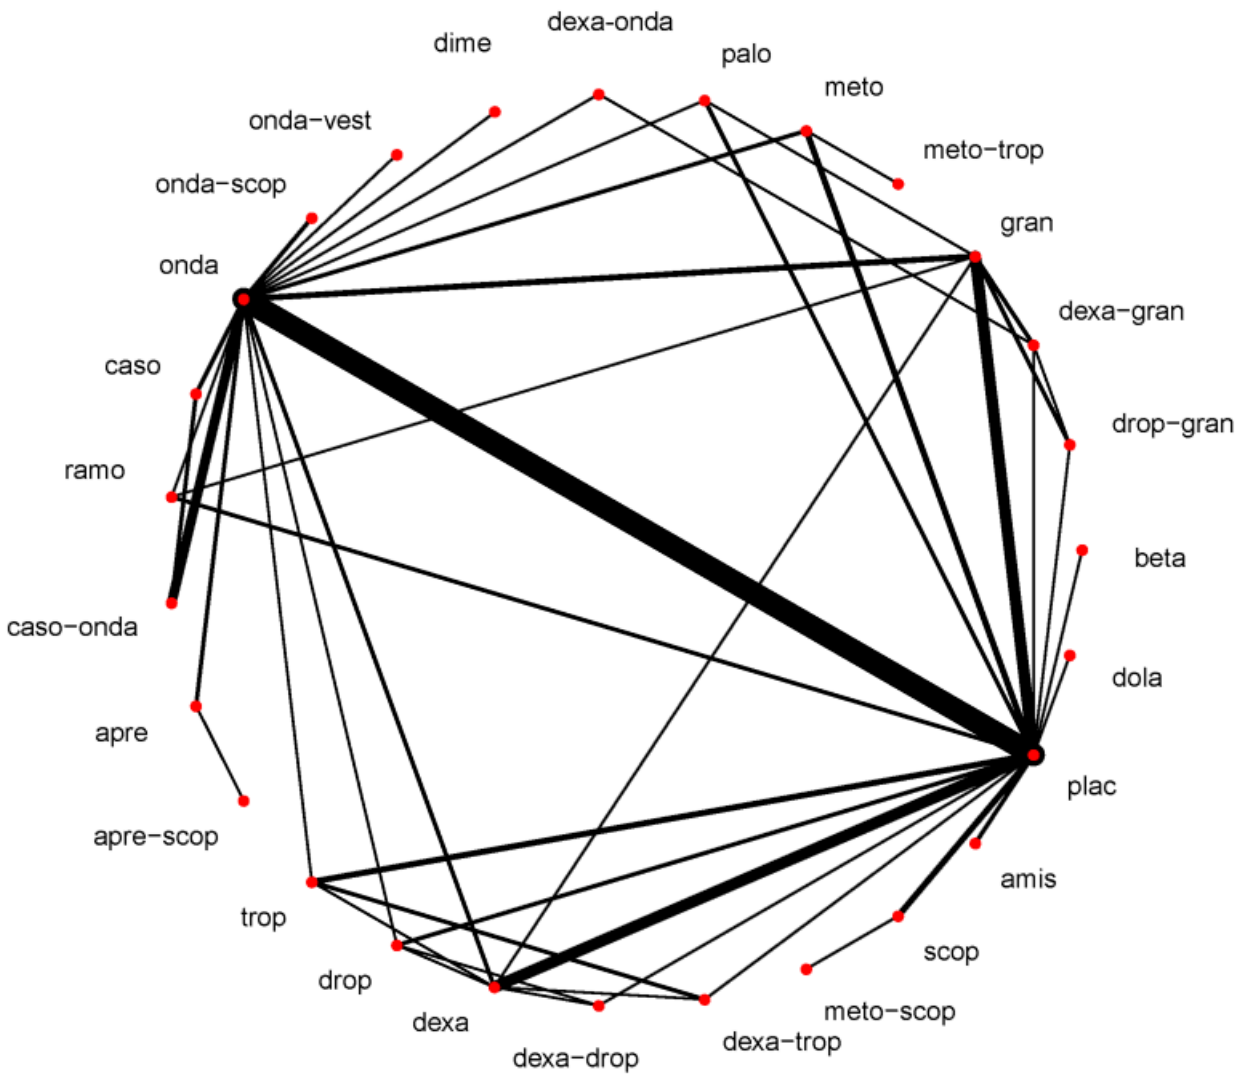
Primary analysis of any AE: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome any AE are available in an online repository (Supplementary Files-3-any AE *; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).*

Sixty-one studies with 93 pair-wise comparisons due to multi-arm studies and 19,423 participants were eligible for the network meta-analysis of any AE. Four studies (7%) have reported zero events in all study arms. The network included 27 treatments (nodes), of which placebo (k = 47) and ondansetron (k = 39) were the most frequent comparators (Figure 12). Of the 27 treatments, 11 were two-fold drug combinations, 15 were single drugs, and one was placebo or no treatment. The most common comparisons were ondansetron (k = 12 studies), dexamethasone (k = 6), granisetron (k = 6), metoclopramide (k = 3), scopolamine (k = 3), and tropisetron (k = 3), all compared to placebo, and casopitant-ondansetron (k = 5) and granisetron (k = 3) compared to ondansetron. Of the single drugs of direct interest, amisulpride, dolasetron, and scopolamine were connected only to placebo, and aprepitant and dimenhydrinate were connected only to ondansetron.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Figure 12. Network geometry of eligible comparisons for any adverse event (any AE) within 7 days postoperatively. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



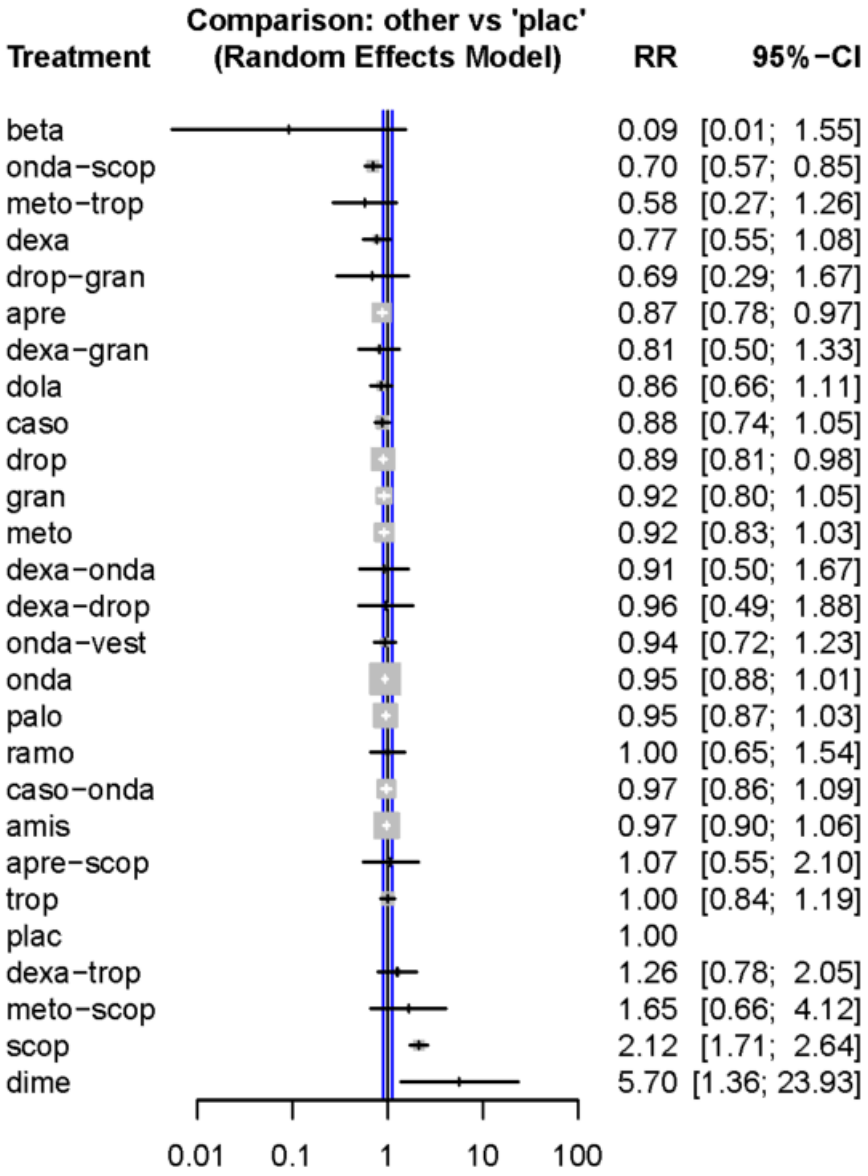
For 27 treatments, 351 comparisons are possible, and the results of all network estimates are available in the online repository. For 35 of 351 comparisons, direct and indirect evidence was available, whereas for 12 comparisons, only direct evidence was available, and for 304 comparisons, only indirect evidence was available.

Relative efficacy presented as summary relative effects (risk ratio, RR) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 13. Of the 15 single drugs, scopolamine and dimenhydrinate showed important harm (95% CI lower boundary > 1.11) compared to placebo, with RRs of 2.12 (95% CI 1.71 to 2.64) and 5.70 (95% CI 1.36 to 23.93), respectively. Amisulpride (RR 0.97, 95% CI 0.90 to 1.06) showed no or minimal effect on any AE compared to placebo. Six single treatments showed benefit (betamethasone, dexamethasone, aprepitant, dolasetron, casopitant, droperidol), another six treatments showed no or minimal effect (granisetron, metoclopramide, ondansetron, palonosetron, ramosetron, tropisetron), and all 12 of these treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs compared to placebo ranged between RR 0.09 (95% CI 0.01

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

to 1.55) for betamethasone and RR 5.70 (95% CI 1.36 to 23.93) for dimenhydrinate. The only combination treatment showing important benefit compared to placebo (95% CI upper boundary < 0.9) was ondansetron-scopolamine with RR of 0.70 (95% CI 0.57 to 0.85). Of the other combination treatments compared to placebo, three combinations showed benefit (metoclopramide-tropisetron, droperidol-granisetron, dexamethasone-granisetron), five showed no or minimal effect (dexamethasone-ondansetron, dexamethasone-droperidol, ondansetron-vestipitant, casopitant-ondansetron, aprepitant-scopolamine), two showed harm (dexamethasone-tropisetron, metoclopramide-scopolamine), and all treatment effects were associated with uncertainty. Treatment effects of drug combinations compared to placebo ranged between RR 0.70 (95% CI 0.57 to 0.85) for ondansetron-scopolamine and RR 1.65 (95% CI 0.66 to 4.12) for metoclopramide-scopolamine.

Figure 13. Forest plot of network meta-analysis of all trials for any adverse events (any AE) within 7 days postoperatively. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to 1.11). Treatments are ranked according to safety based on P scores. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

The estimated value of between-study variance for the network meta-analysis of any AE was 0 (tau^2) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 25.27, df = 22, P = 0.28) and no inconsistency between designs (Q = 19.59, df = 28, P = 0.88). Clinically relevant heterogeneity for relevant comparisons (single drugs of direct interest compared to placebo) was detected only for dolasetron because the 95% PI included a different clinical implication compared to the 95% CI. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed no significant disagreement (direct versus indirect) for any of the 35 comparisons. There was no clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo.

Sensitivity analyses of any AE

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of any AE: risk of bias

Nine (15%) of 61 studies were rated as having high risk of overall bias, 31 (51%) as unclear, and 21 (34%) as low. The sensitivity network meta-analysis including only studies at low risk of bias revealed a poorly connected network, including 18 treatments. Six treatments were two-fold combinations of antiemetic drugs, 11 were single drugs, and one was placebo. Of the single drugs of direct interest included in the primary network meta-analysis of any AE, dolasetron, palonosetron, dimenhydrinate, and scopolamine were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Of the 11 single drugs, four drugs showed important benefit compared to placebo (aprepitant, casopitant, ondansetron, metoclopramide), with RRs ranging between 0.50 (95% CI 0.30 to 0.82) for aprepitant and 0.54 (95% CI 0.33 to 0.89) for metoclopramide. None of the four drugs showed important benefit compared to placebo in the primary network meta-analysis. Proof of data revealed one small outlier study comparing ondansetron versus placebo with extreme positive effects for ondansetron (Koyuncu 2017). Excluding Koyuncu 2017 and redoing the sensitivity analysis for risk of bias revealed that none of the treatments maintained important benefit compared to placebo. Thus, favourable effects for aprepitant, casopitant, ondansetron, and metoclopramide in the first sensitivity analysis for risk of bias may be due to strong effects reported by Koyuncu 2017.

Comparison of treatment effects of the sensitivity analysis for risk of bias without Koyuncu 2017, and the primary network meta-analysis for any AE revealed seven drugs compared to placebo with non-robust treatment effects (ramosetron, aprepitant, casopitant, droperidol, dexamethasone, ondansetron, metoclopramide). Ramosetron compared to placebo with RR 0.79 (95% CI 0.26 to 2.41) showed benefit with uncertainty. Aprepitant and casopitant compared to placebo, with RR 1.00 (95% CI 0.48 to 2.09) and RR 1.02 (95% CI 0.47 to 2.19), respectively, showed no or minimal effect associated with uncertainty. Droperidol compared to placebo, with RR 1.32 (95% CI 0.64 to 2.72), showed harm associated with uncertainty. For dexamethasone, ondansetron, and metoclopramide, the uncertainty of effect estimates was increased further in the sensitivity analysis compared to the primary network meta-analysis. The estimated value of between-study variance for the sensitivity network meta-analysis of any AE was 0 (tau^2) (I^2 = 0%).

Sensitivity analysis of any AE: risk of bias for monitoring and reporting of any AE

In a sensitivity network meta-analysis for monitoring and reporting of any AE, we included only studies that were assessed as low risk of bias with respect to monitoring and reporting for any AE. We assessed 11 (18%) of 61 studies as having low risk of bias for monitoring and reporting of any AE. The network including only studies at low risk of bias was poorly connected, with two sub-networks that were connected only via the route ondansetron to placebo. Of the single drugs of direct interest, dolasetron, droperidol, metoclopramide, palonosetron, amisulpride, tropisetron, and dimenhydrinate were not included in the sensitivity network meta-analysis due to lack of studies assessed as low risk. Treatment effects of three drugs compared to placebo were not robust in this sensitivity analysis (aprepitant, casopitant, ramosetron). Aprepitant (RR 0.97, 95% CI 0.82 to 1.16) and casopitant (RR 0.99, 95% CI 0.76 to 1.29) showed no or minimal effect on any AE associated with uncertainty. Ramosetron with RR 1.31 (95% CI 0.73 to 2.38) showed harm associated with uncertainty. The estimated value of between-study variance for the sensitivity network meta-analysis of any AE was 0 (tau^2) (I^2 = 0%).

Sensitivity analysis of any AE: imbalance in baseline details and/or risk factors for PONV in study participants

We assessed studies with an imbalance in baseline details and/or risk factors for PONV between the study arms as having high risk of other bias. For any AE, five (8%) of 61 studies were rated as having high risk of other bias, 48 (77%) as unclear, and eight (13%) as low. One study was not connected to the network (Chen 2006; comparison: dexamethasone versus placebo). The remaining seven studies with low risk of other bias with six treatments were poorly connected in one network in which placebo was not used as a comparator. We could not perform a network meta-analysis with placebo as reference compound.

Sensitivity analysis of any AE: studies with PONV-related primary outcome(s)

Thirty-four (56%) of 61 studies have defined a PONV-related primary outcome in their published study report. The network of this sensitivity analysis consisted of 21 treatments including placebo with 11 single drug treatments. Of the single drugs of direct interest, dolasetron, scopolamine, and dimenhydrinate were not included in this network due to lack of studies reporting a PONV-related primary outcome. Treatment effects of four drugs compared to placebo were not robust in this sensitivity analysis (ramosetron, droperidol, aprepitant, casopitant). Ramosetron with RR 0.74 (95% CI 0.32 to 1.73) showed benefit associated with uncertainty. Droperidol (RR 0.93, 95% CI 0.84 to 1.02), aprepitant (RR 0.94, 95% CI 0.83 to 1.07), and casopitant (RR 0.95, 95% CI 0.79 to 1.14) showed no or minimal effect on any AE associated with uncertainty. The estimated value of between-study variance for the sensitivity network meta-analysis of any AE was 0 (tau^2) (I^2 = 0%).

Sensitivity analysis of any AE: funding source

Twenty-seven (44%) of 61 studies were funded by industry, nine (15%) were funded by non-industrial resources, and for another 25 studies (41%), information on funding source was not provided. Two sensitivity analyses—one for industry-funded and one for non-industry-funded studies—were performed. The network of the sensitivity analysis including only industry-funded studies consisted of 26 studies with 16 treatments,

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

including 10 single drugs. One study was not connected to the network and was excluded from the analyses (Gan 2005; comparison: dexamethasone-granisetron versus dexamethasone-ondansetron). Compared to the primary analysis, of the 10 single drugs, treatment effects of four drugs compared to placebo were not robust (droperidol, aprepitant, casopitant, metoclopramide). Droperidol (RR 0.91, 95% CI 0.83 to 1.00), aprepitant (RR 0.92, 95% CI 0.82 to 1.04), and casopitant (RR 0.93, 95% CI 0.78 to 1.11) showed no or minimal effect with uncertainty compared to placebo. Metoclopramide showed harm associated with uncertainty (RR 1.13, 95% CI 0.59 to 2.16). The network of the sensitivity analysis including only studies funded by non-industrial resources consisted of nine studies with nine treatments, including seven single drugs and placebo. Treatment effects for five of the nine drugs compared to placebo were not robust (ramosetron, palonosetron, metoclopramide, granisetron, ondansetron). Ramosetron (RR 0.16, 95% CI 0.01 to 3.13), palonosetron (RR 0.24, 95% CI 0.01 to 4.04), metoclopramide (RR 0.48, 95% CI 0.02 to 9.27), granisetron (RR 0.49, 95% CI 0.03 to 9.38), and ondansetron (RR 0.48, 95% CI 0.06 to 3.75) showed benefit associated with uncertainty compared to placebo.

Six single drugs were funded only by industry (droperidol, aprepitant, casopitant, amisulpride, tropisetron, scopolamine), and three solely by non-industrial resources (betamethasone, ramosetron, dexamethasone). Four single drugs (ondansetron, granisetron, metoclopramide, palonosetron) were investigated in studies funded by either of the sources and treatment effects were not robust, with treatment effects being more favourable in non-industry-funded studies. For two drugs (dimenhydrinate, dolasetron), the funding source was not specified.

Reporting bias (any AE)

The only pair-wise comparison including 10 or more studies was ondansetron versus placebo, for which small-study effects such as reporting or publication bias were investigated. Results of the funnel plot, the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. According to the explorative analyses, we did not suspect publication bias for ondansetron versus placebo (P = 0.19).

Subgroup analysis of any AE: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis including single drugs only (and excluding combination treatments) with 48 studies and 16 treatments including placebo was conducted. Network geometry, effect estimates, and the ranking order of drugs with placebo as comparator were comparable to the primary analysis, including combination prophylaxis. The estimated value of between-study variance for the network meta-analysis of single drugs for any AE was 0 (tau^2) (I^2 = 0%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. The following drugs were split into dose categories: amisulpride, aprepitant, dexamethasone, granisetron, ondansetron, palonosetron, ramosetron, and tropisetron. For casopitant, dimenhydrinate, dolasetron, droperidol, and metoclopramide, only one dose category was available for subgroup analysis. Drugs without any dose recommendation according to Table 1 (scopolamine) and drugs not of direct interest (betamethasone) were included in the analysis and were lumped together, irrespective of the doses being analysed, in the category 'NA'. Wagner 1996 and one arm of Bhatnagar 2007 (granisetron NA) were excluded from the subgroup analysis because they were not associated with one of the three dose categories. The network consisted of 47 studies with 16 treatments split into 29 nodes with dose categories and is presented in the online repository. In the ranking of treatments according to safety with placebo as comparator, high or recommended doses of dexamethasone, ondansetron, palonosetron, ramosetron, and granisetron ranked higher compared to recommended or low doses, respectively. All 95% CIs between different doses of the same drug were overlapping. Tropisetron used as recommended ranked over high and low doses, but 95% CIs included both benefit and harm. High and recommended doses of aprepitant compared to placebo had similar treatment effects.

Additivity of dose categories (any AE)

A network meta-analysis with the assumption of additivity of dose categories revealed no differences between standard and additive models (P = 0.96), suggesting additive dose effects.

Sensitivity analysis of any AE: comparability of doses

In 31 (51%) of 61 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis was poorly connected, consisting of 12 treatments including placebo, which limited available evidence. Of single drugs of direct interest included in the primary network meta-analysis, aprepitant, dimenhydrinate, and scopolamine were not included in the sensitivity analysis due to lack of studies with comparable doses. Treatment effects of ramosetron and metoclopramide compared to placebo were not robust in the sensitivity analysis. Ramosetron (RR 0.54, 95% CI 0.24 to 1.20) and metoclopramide (RR 0.61, 95% CI 0.31 to 1.20) showed benefit associated with uncertainty. The estimated value of between-study variance for this sensitivity network meta-analysis of any AE was 0.0069 (tau^2) (I^2 = 24.5%).

Additive effects of combinations of treatments (any AE)

We tested the hypothesis of additivity of the components in combination prophylaxis by comparing the primary standard network meta-analysis (k = 61) with a second analysis, which assumes that the effects of combined treatments are additive sums of their components. Standard and additive models were different (P < 0.0001), suggesting no additive effects of components.

Certainty of evidence: any AE

The certainty of evidence of treatment estimates for any AE evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 4).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for any

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

AE ranged from very low to moderate (Summary of findings 4). Granisetron (RR 0.92, 95% CI 0.80 to 1.05) probably has little or no effect on any AE compared to placebo, with moderate-certainty evidence (imprecision). Ondansetron (RR 0.95, 95% CI 0.88 to 1.01) and palonosetron (RR 0.95, 95% CI 0.87 to 1.03) may have little or no effect on any AE compared to placebo, with low-certainty evidence (study limitations, imprecision). Tropisetron (RR 1.00, 95% CI 0.84 to 1.19) may also have little or no effect on any AE compared to placebo, as certainty of evidence has been assessed as low (very serious concerns for imprecision). We are uncertain whether ramosetron (RR 1.00, 95% CI 0.65 to 1.54) has little or no effect on any AE compared to placebo, with very low-certainty evidence (study limitations, very serious concerns for imprecision). We are uncertain whether dolasetron (RR 0.86, 95% CI 0.66 to 1.11), with direct evidence only, reduces any AE compared to placebo, with very low-certainty evidence (very serious concern for study limitations, imprecision-heterogeneity).

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for any AE was assessed as low to moderate (Summary of findings 4). Amisulpride (RR 0.97, 95% CI 0.90 to 1.06), with direct evidence only, probably has little or no effect on any AE compared to placebo, with moderate-certainty evidence (imprecision). Droperidol (RR 0.89, 95% CI 0.81 to 0.98) may reduce any AE compared to placebo, with low-certainty evidence (study limitations, imprecision). Metoclopramide (RR 0.92, 95% CI 0.83 to 1.03) may have little or no effect on any AE, with low-certainty evidence (study limitations, imprecision). No studies reporting any AE were available for haloperidol or perphenazine.

For relevant NK_1 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for any AE was assessed as very low (Summary of findings 4). We are uncertain whether casopitant (RR 0.88, 95% CI 0.74 to 1.05) and aprepitant (RR 0.87, 95% CI 0.78 to 0.97), with indirect evidence only, reduce any AE compared to placebo (study limitations, imprecision, incoherence). No studies reporting any AE were available for fosaprepitant and rolapitant.

The only corticosteroid that was included in the network meta-analysis for any AE was dexamethasone (RR 0.77, 95% CI 0.55 to 1.08), which may reduce any AE compared to placebo, with low-certainty evidence (study limitations, imprecision) (Summary of findings 4). No studies reporting any AE were available for methylprednisolone.

The only antihistamine that was included in the network meta-analysis for any AE was dimenhydrinate (RR 5.70, 95% CI 1.36 to 23.93), which may increase any AE compared to placebo, with direct evidence only and low certainty (study limitations, incoherence) (Summary of findings 4). No studies reporting any AE were available for promethazine or meclizine.

The anticholinergic scopolamine (RR 2.12, 95% CI 1.71 to 2.64) may increase any AE compared to placebo, with only direct evidence of low certainty (very serious concerns for study limitations) (Summary of findings 4).

Secondary outcomes (GRADE-relevant)

Headache within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of headache

Pairwise meta-analyses of headache comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for amisulpride (Analysis 1.4), aprepitant (Analysis 2.2), dexamethasone (Analysis 3.4), dimenhydrinate (Analysis 4.2), dolasetron (Analysis 5.4), droperidol (Analysis 6.4), granisetron (Analysis 7.4), haloperidol (Analysis 8.2), metoclopramide (Analysis 10.3), ondansetron (Analysis 11.4), palonosetron (Analysis 12.4), promethazine (Analysis 14.2), ramosetron (Analysis 15.4), scopolamine (Analysis 17.4), and tropisetron (Analysis 18.4). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

Primary analysis of headache: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome headache are available in an online repository (Supplementary Files-4-headache *; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).*

In total, 208 studies with 426 pair-wise comparisons due to multi-arm studies and 42,445 participants were eligible for the network meta-analysis of headache. Twenty studies (10%) have reported zero events in all study arms. The network included 53 treatments (nodes) (Figure 14), with 29 drug combinations, 23 single drugs, and placebo or no treatment. The most common comparisons involved ondansetron (k = 57 studies), droperidol (k = 22), granisetron (k = 15), ramosetron (k = 14), and dexamethasone (k = 13), all compared to placebo. Of the single drugs of direct interest, amisulpride and scopolamine were poorly connected to the network, with placebo as the only comparator.

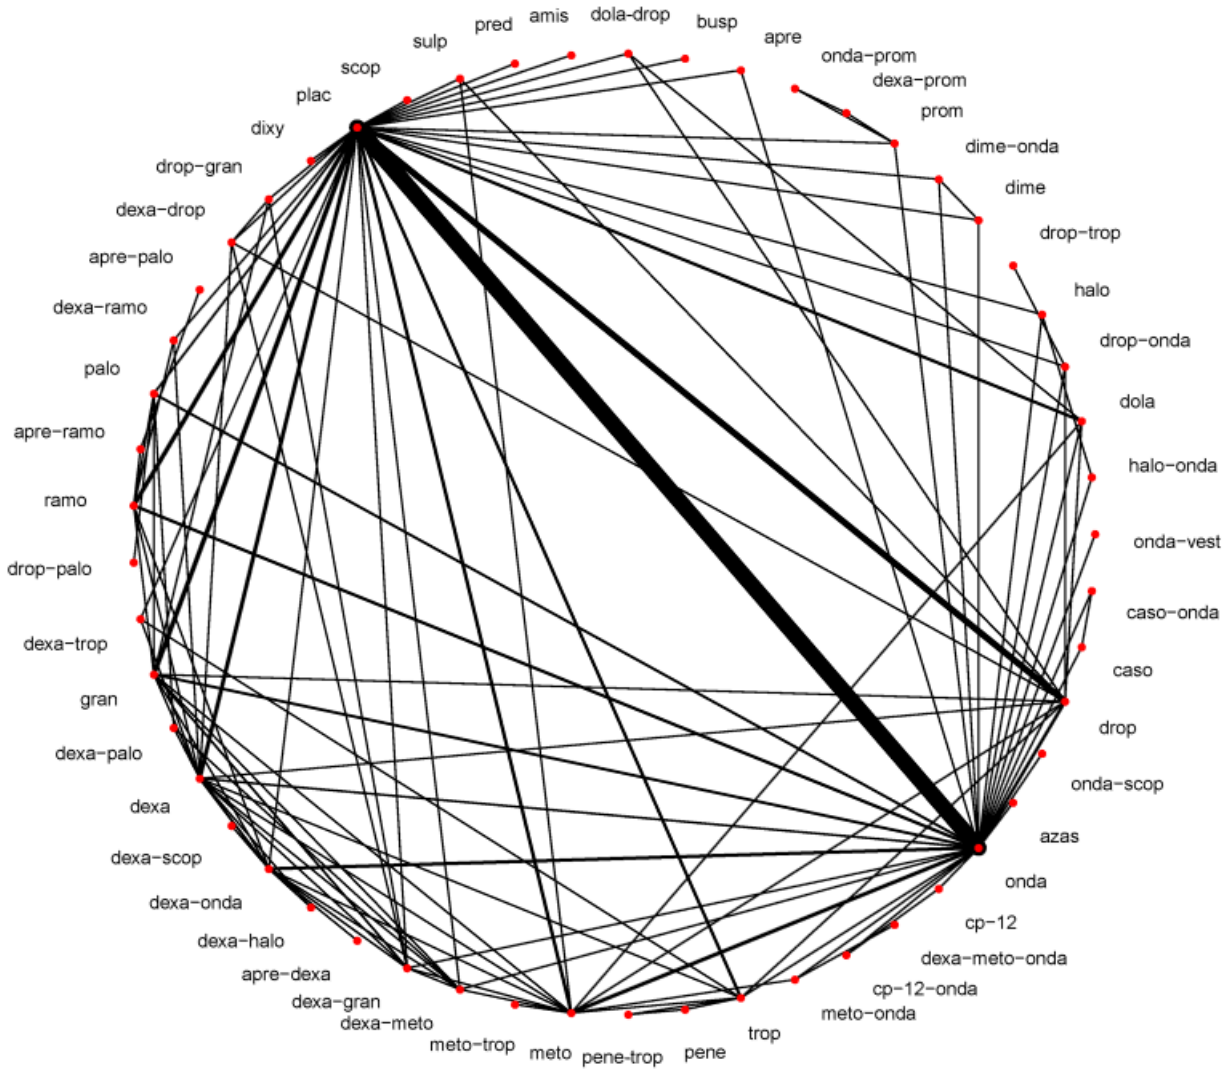
Figure 14. Network geometry of eligible comparisons for postoperative headache. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



For 53 different treatments, 1378 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 96 of 1378 comparisons, direct and indirect evidence was available, whereas for 26 comparisons, only direct evidence was available, and for 1256 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (risk ratio, RR) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 15. Of the 23 single drugs, sulpiride and droperidol showed important benefit (95% CI upper boundary < 0.9) in terms of headache compared to placebo, with RRs of 0.10 (95% CI 0.01 to 0.71) and 0.76 (95% CI 0.67 to 0.86), respectively. Eight single treatments showed benefit (haloperidol, promethazine, prednisolone, penehyclidine, casopitant, dexamethasone, azasetron, aprepitant), three showed no or minimal effect (metoclopramide, scopolamine, tropisetron), 10 showed harm (dimenhydrinate, dolasetron, ramosetron, palonosetron, ondansetron, granisetron, dixyrazine, buspirone, amisulpride, CP-122,721), and all 21 of these treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs ranged between RR 0.10 (95% CI 0.01 to 0.71) for amisulpride and RR 5.82 (95% CI

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

0.70 to 48.25) for CP-122,721. Of all combination treatments, the only combination treatment showing important benefit compared to placebo was droperidol-tropisetron, with RR of 0.20 (95% CI 0.05 to 0.84). Of the other combination treatments, 15 combinations showed benefit, seven showed no or minimal effect, six showed harm, and all treatment effects were associated with uncertainty. Treatment effects of drug combinations compared to placebo ranged between RR 0.20 (95% CI 0.05 to 0.84) for droperidol-tropisetron and RR 3.43 (95% CI 0.37 to 31.96) for CP-122,721-ondansetron.

Figure 15. Forest plot of network meta-analysis of all trials for postoperative headache. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to

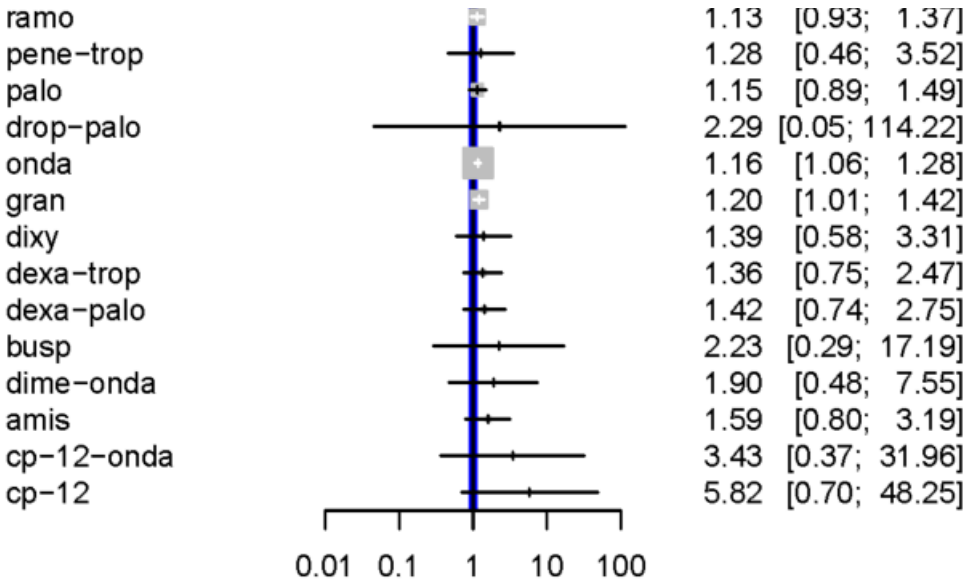
Figure 15. (Continued)



The estimated value of between-study variance for the network meta-analysis of headache was 0 (tau^2) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 82.42, df = 126, P = 1.00) and no inconsistency between designs (Q = 86.57, df = 126, P = 1.00). No clinically relevant heterogeneity for relevant comparisons (single drugs of direct interest compared to placebo) was detectable because 95% CIs and 95% PIs were compatible with respect to the range of equivalence. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed disagreement (direct versus indirect) for five out of 96 comparisons, namely, dexamethasone-granisetron versus dexamethasone (P = 0.045), dolasetron-droperidol versus droperidol (P = 0.01), droperidol versus amisulpride (P = 0.04), ondansetron versus palonosetron (P = 0.005), and amisulpride versus placebo (P = 0.01). Clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo was found only for granisetron (95% CI direct estimate: 1.03 to 1.61; 95% CI indirect estimate: 0.83 to 1.41).

Sensitivity analyses of headache

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of headache: risk of bias

Twenty-five (12%) of 208 studies were rated as high risk of overall bias, 121 (58%) as unclear, and 62 (30%) as low. One study with low risk of bias was not connected to the network of low risk of bias studies and was excluded from the sensitivity analyses (DeOliveira 2011; comparison: dexamethasone-metoclopramide-ondansetron versus metoclopramide-ondansetron). The network geometry of the remaining 61 studies at low risk of bias included 32 treatments. Thirteen treatments were two-fold combinations of antiemetic drugs, 18 were single drugs, and one was placebo. Of the single drugs of direct interest included in the primary network meta-analysis of headache, promethazine, scopolamine, and dimenhydrinate were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Comparison of treatment effects of the sensitivity analysis for risk of bias and the primary network meta-analysis for headache with placebo as common comparator revealed eight single drugs of direct interest with non-robust treatment effects (droperidol, tropisetron, dolasetron, ramosetron, palonosetron, metoclopramide, granisetron, haloperidol). Droperidol and tropisetron, with RR 0.79 (95% CI 0.58 to 1.07) and RR 0.82 (95% CI 0.25 to 2.69), respectively, showed benefit with uncertainty compared to placebo. Dolasetron, ramosetron, and palonosetron, with RR 1.02 (95% CI 0.65 to 1.60), RR 1.08 (95% CI 0.82 to 1.41), and RR 1.09 (95% CI 0.75 to 1.60), respectively, showed no or minimal effect associated with uncertainty compared to placebo. Metoclopramide compared to placebo, with RR 1.23 (95% CI 0.51 to 2.96), showed harm associated with uncertainty. For granisetron with RR 1.12 (95% CI 0.63 to 1.97) and haloperidol with RR 0.40 (95% CI 0.04 to 4.13), the uncertainty of effect estimates was increased further in the sensitivity analysis compared to the primary network meta-analysis. The estimated value of between-study variance for the sensitivity network meta-analysis of headache was 0 (tau^2) (I^2 = 0%).

Reporting bias (headache)

Twelve direct pair-wise comparisons included 10 of more studies for which small-study effects such as reporting or publication bias were investigated: dexamethasone, dolasetron, droperidol, granisetron, metoclopramide, ondansetron, ramosetron, and tropisetron, all compared to placebo; and dexamethasone-ondansetron, droperidol, metoclopramide, and ramosetron, all compared to ondansetron. Results of the funnel plots, the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. We did not suspect relevant publication bias for any of the comparisons mentioned above. The only P value < 0.1 was revealed for droperidol versus ondansetron (P = 0.047). However, we did not suspect relevant publication bias because trim and fill sensitivity analysis did not change the conclusion with respect to the range of equivalence.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Subgroup analysis of headache: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis including single drugs only (and excluding combination treatments) with 176 studies and 24 treatments including placebo was conducted. Network geometry, effect estimates, and the ranking order of drugs were robust compared to the primary analysis, including combination prophylaxis, except for dexamethasone compared to placebo, with RR 0.91 (95% CI 0.67 to 1.23) showing no or minimal effect with uncertainty. The estimated value of between-study variance for the network meta-analysis of single drugs for headache was 0 (tau^2) (I^2 = 0%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. The following drugs were split into dose categories: amisulpride, aprepitant, dexamethasone, dolasetron, droperidol, granisetron, haloperidol, ondansetron, palonosetron, ramosetron, and tropisetron. For casopitant, dimenhydrinate, metoclopramide, and promethazine, only one dose category was available for subgroup analysis. Drugs without any dose recommendation according to Table 1 (scopolamine) and drugs not of direct interest (azasetron, buspirone, CP-122,721, dixyrazine, penehyclidine, prednisolone, amisulpride) were included in the analysis and were lumped together, irrespective of the doses being analysed, in the category 'NA'. Five studies—Diemunsch 1998; Eberhart 2006; Jokela 2002; Prescott 1976; Warriner 1997—and one arm each of Bhatnagar 2007 (granisetron NA), Lee D 2009 (ramosetron NA), and Turhanoglu 1999 (dimenhydrinate NA) were excluded from the subgroup analysis because they were not associated with one of the three dose categories. The network consisted of 171 studies with 24 treatments split into 42 nodes with dose categories and is presented in the online repository. In the treatment ranking according to safety, with placebo as the reference compound, high and recommended doses of ramosetron, droperidol, granisetron, dexamethasone, tropisetron, and ondansetron ranked higher than low doses. However, all 95% CIs between different doses of the same drug overlapped, and the uncertainty of treatment effects was considerable. All doses of amisulpride and palonosetron compared to placebo showed harm with uncertainty. Both recommended and high doses of haloperidol compared to placebo showed benefit with uncertainty, and both recommended and high doses of dolasetron compared to placebo showed no or minimal effect associated with uncertainty. Recommended doses of aprepitant ranked higher than high doses compared to placebo. However, treatment effects were associated with uncertainty.

Sensitivity analysis of headache: comparability of doses

In 102 (51%) of 176 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis consisted of 15 treatments including placebo. Of single drugs of direct interest included in the primary network meta-analysis, dimenhydrinate and scopolamine were not included in the sensitivity analysis due to lack of studies with comparable doses. The favourable treatment effect of droperidol compared to placebo remained robust (RR 0.74, 95% CI 0.63 to 0.87). Treatment effects of three drugs (ramosetron, dexamethasone, tropisetron) compared to placebo were not robust in the sensitivity analysis. Ramosetron compared to placebo (RR 0.98, 95% CI 0.76 to 1.26) showed no or minimal effect associated with uncertainty. Dexamethasone (RR 1.25, 95% CI 0.72 to 2.16) and tropisetron (RR 1.48, 95% CI 0.82 to 2.67), compared to placebo, showed harm associated with uncertainty. The estimated value of between-study variance for this sensitivity network meta-analysis of headache was 0 (tau^2) (I^2 = 0%).

Certainty of evidence: headache

The certainty of evidence of treatment estimates for headache evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 5).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for headache ranged from very low to moderate (Summary of findings 5). Ondansetron (RR 1.16, 95% CI 1.06 to 1.28) probably increases headache compared to placebo, with moderate-certainty evidence (imprecision). Ramosetron (RR 1.13, 95% CI 0.93 to 1.37) and dolasetron (RR 1.13, 95% CI 0.93 to 1.36) may increase headache compared to placebo, with low-certainty evidence (study limitations, imprecision). Tropisetron (RR 1.09, 95% CI 0.91 to 1.32) may have little or no effect on headache compared to placebo, with low-certainty evidence (study limitations, imprecision). We are uncertain whether granisetron (RR 1.20, 95% CI 1.01 to 1.42) and palonosetron (RR 1.15, 95% CI 0.89 to 1.49) increase headache compared to placebo, with very low-certainty evidence (granisetron: study limitation, imprecision, incoherence; palonosetron: study limitation, very serious concerns for imprecision).

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for headache was assessed as very low to moderate (Summary of findings 5). Droperidol (RR 0.76, 95% CI 0.67 to 0.86) probably reduces headache compared to placebo, with moderate-certainty evidence (study limitations). Haloperidol (RR 0.54, 95% CI 0.27 to 1.06) may reduce headache compared to placebo, with low-certainty evidence (study limitation, imprecision). Amisulpride (RR 1.59, 95% CI 0.80 to 3.19), with direct evidence only, may increase headache compared to placebo, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether metoclopramide (RR 0.93, 95% CI 0.76 to 1.13) has little or no effect on headache compared to placebo, with very low-certainty evidence (study limitations, very serious concerns for imprecision). No studies reporting headache were available for perphenazine.

For relevant NK_1 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for headache was assessed as very low to low (Summary of findings 5). Aprepitant (RR 0.86, 95% CI 0.35 to 2.11) may reduce headache compared to placebo, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether casopitant (RR 0.81, 95% CI 0.49 to 1.34), with indirect evidence only, reduces headache, with very low-certainty evidence (incoherence, very serious concerns for imprecision). No studies reporting headache were available for fosaprepitant or rolapitant.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

The only corticosteroid that was included in the network meta-analysis for headache was dexamethasone (RR 0.85, 95% CI 0.63 to 1.13), which may reduce headache compared to placebo, with low-certainty evidence (very serious concerns for imprecision) (Summary of findings 5). No studies reporting headache were available for methylprednisolone.

For relevant antihistamines (compared to placebo), the certainty of evidence of network effect estimates for headache was assessed as very low (Summary of findings 5). We are uncertain whether dimenhydrinate (RR 1.23, 95% CI 0.33 to 4.55) increases or promethazine (RR 0.27, 95% CI 0.01 to 4.83) reduces headache compared to placebo (study limitations, very serious concerns for imprecision). No studies reporting headache were available for meclizine.

We are uncertain whether the anticholinergic scopolamine (RR 1.03, 95% CI 0.55 to 1.94) has little or no effect on headache compared to placebo, with only direct evidence of very low certainty (very serious concerns for study limitations and imprecision) (Summary of findings 5).

Sedation within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of sedation

Pairwise meta-analyses of sedation comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for amisulpride (Analysis 1.5), dexamethasone (Analysis 3.5), dimenhydrinate (Analysis 4.3), dolasetron (Analysis 5.5), droperidol (Analysis 6.5), granisetron (Analysis 7.5), methylprednisolone (Analysis 9.1), metoclopramide (Analysis 10.4), ondansetron (Analysis 11.5), palonosetron (Analysis 12.5), perphenazine (Analysis 13.1), promethazine (Analysis 14.3), ramosetron (Analysis 15.5), scopolamine (Analysis 17.5), and tropisetron (Analysis 18.5). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

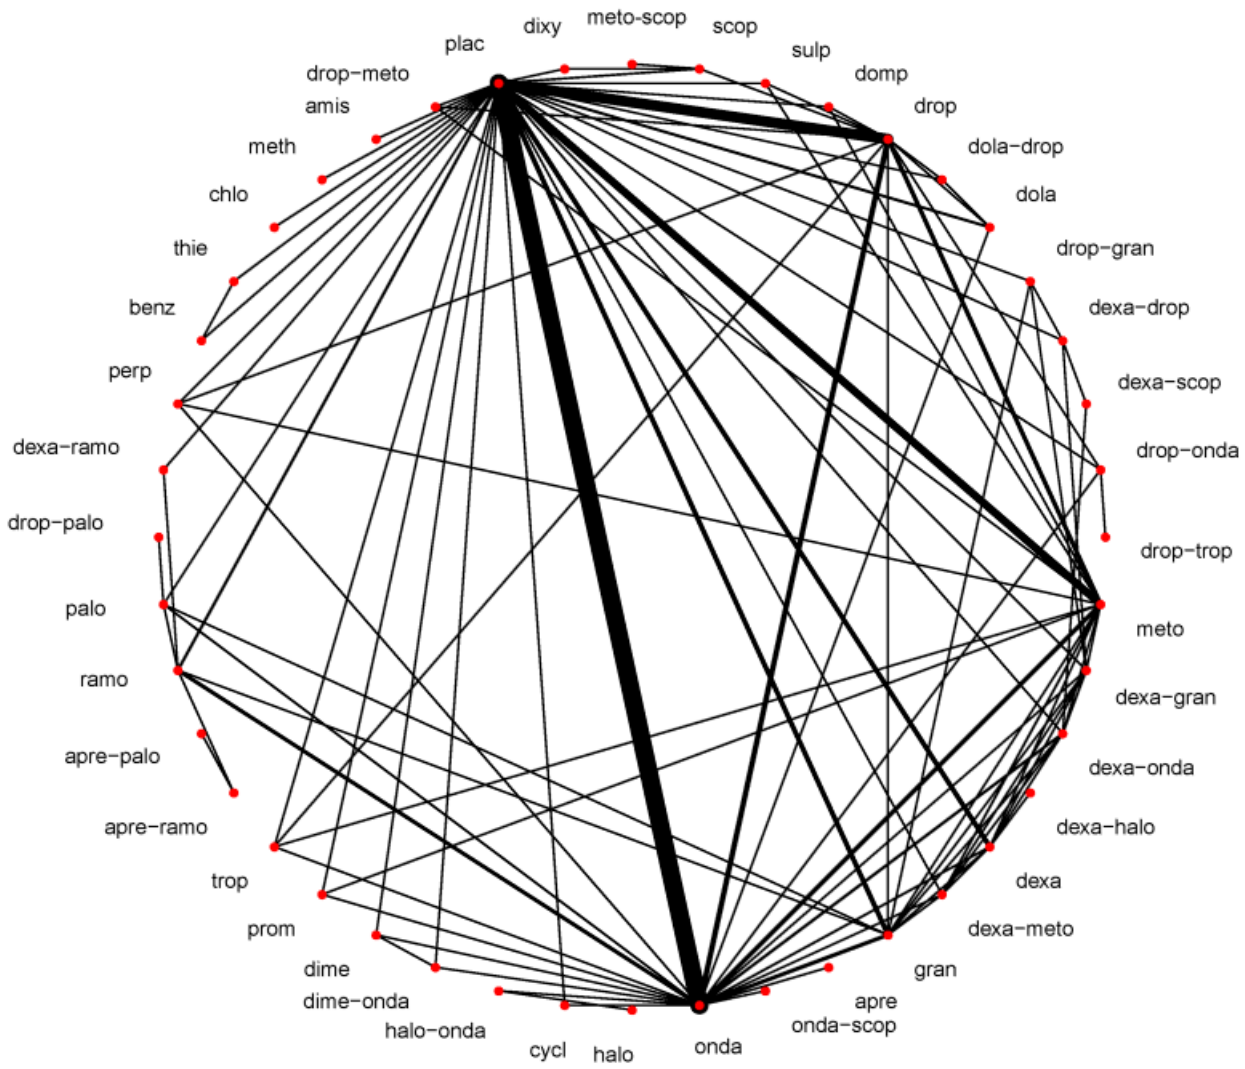
Primary analysis of sedation: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome sedation are available in an online repository (Supplementary Files-5-sedation *; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).*

In total, 117 studies with 280 pair-wise comparisons due to multi-arm studies and 21,440 participants were eligible for the network meta-analysis of sedation. Nineteen studies (16%) have reported zero events in all study arms. The network included 44 treatments (nodes) (Figure 16), with 19 drug combinations, 24 single drugs, and 1 placebo or no treatment. The most common comparisons were ondansetron (k = 36 studies), droperidol (k = 21), and metoclopramide (k = 15), all compared to placebo, and droperidol, compared to ondansetron (k = 10). Of the single drugs of direct interest, amisulpride and methylprednisolone were poorly connected to the network, with placebo as the only comparator.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Figure 16. Network geometry of eligible comparisons for postoperative sedation. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



For 44 different treatments, 946 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 89 of 946 comparisons, direct and indirect evidence was available, whereas for 16 comparisons, only direct evidence was available, and for 841 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (risk ratio, RR) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 17. In terms of sedation, only amisulpride out of the 24 single drugs showed important benefit (95% CI upper boundary < 0.9) compared to placebo, with RR of 0.03 (95% CI 0.00 to 0.50), and three drugs showed important harm (95% CI lower boundary > 1.11), namely,dimenhydrinate (RR 7.66, 95% CI 3.10 to 18.94), benzquinamide (RR 36.78, 95% CI 2.26 to 599.50), and thiethylperazine (RR 51.38, 95% CI 3.18 to 830.62). Seven single treatments showed benefit (dixyrazine, perphenazine, tropisetron, ondansetron, aprepitant, domperidone, ramosetron), nine showed no or minimal effect (haloperidol, metoclopramide, droperidol, chlorpromazine, amisulpride, dolasetron, granisetron, dexamethasone, promethazine), four showed harm (cyclizine, palonosetron, scopolamine, methylprednisolone), and all 20 of these treatment effects were associated with uncertainty (95% CI

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

crossing the range of equivalence). Treatment effects of all single drugs ranged between RR 0.03 (95% CI 0.00 to 0.50) for amisulpride and RR 51.38 (95% CI 3.18 to 830.62) for thiethylperazine. Of the 19 drug combinations, the only combination showing important benefit compared to placebo was dexamethasone-metoclopramide (RR 0.41, 95% CI 0.24 to 0.71) and the only combination treatment with important harm compared to placebo was dimenhydrinate-ondansetron (RR 6.90, 95% CI 2.74 to 17.32). Of the other combination treatments, five combinations showed benefit, another five showed no or minimal effect, eight showed harm, and all treatment effects were associated with uncertainty. Treatment effects of drug combinations compared to placebo ranged between RR 0.41 (95% CI 0.24 to 0.71) for dexamethasone-metoclopramide and RR 6.90 (95% CI 2.74 to 17.32) for dimenhydrinate-ondansetron.

Figure 17. Forest plot of network meta-analysis of all trials for postoperative sedation. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to

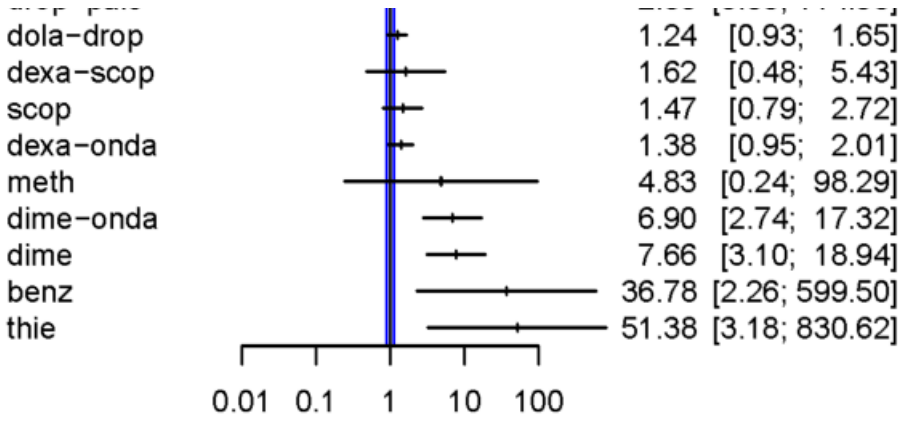
Figure 17. (Continued)



The estimated value of between-study variance for the network meta-analysis of sedation was 0 (tau²) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 30.85, df = 48, P = 0.98) and no inconsistency between designs (Q = 108.63, df = 93, P = 0.13). No clinically relevant heterogeneity for relevant comparisons (single drugs of direct interest compared to placebo) was detectable because 95% CIs and 95% PIs were compatible with respect to the range of equivalence. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed disagreement (direct versus indirect) for 14 out of 89 comparisons. Three out of 14 comparisons with local inconsistency were of direct interest, namely, dexamethasone versus placebo (P = 0.02), droperidol versus placebo (P = 0.0002), and metoclopramide versus placebo (P = 0.04). For both dexamethasone and droperidol versus placebo, there was a contribution of direct evidence greater than 90%; thus there is no concern for incoherence. Clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo was found only for metoclopramide versus placebo (95% CI direct estimate: 0.90 to 1.35; 95% CI indirect estimate: 0.59 to 1.00).

Sensitivity analyses of sedation

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of sedation: risk of bias

Fourteen (12%) of 117 studies were rated as having high risk of overall bias, 75 (64%) as unclear, and 28 (24%) as low. The network geometry of the 28 studies at low risk of bias included 23 treatments. Eight treatments were two-fold combinations of antiemetic drugs, 14 were single drugs, and one was placebo. Of the single drugs of direct interest included in the primary network meta-analysis for sedation, haloperidol, perphenazine, scopolamine, and dimenhydrinate were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Comparison of treatment effects of the sensitivity analysis for risk of bias and the primary network meta-analysis of sedation with placebo as a common comparator revealed seven single drugs of direct interest with non-robust treatment effects (ramosetron, granisetron, palonosetron, droperidol, promethazine, tropisetron, metoclopramide). Granisetron and palonosetron, with RR 0.80 (95% CI 0.21 to 3.07) and RR 0.80 (95% CI 0.04 to 16.76), respectively, showed benefit with uncertainty compared to placebo. Promethazine, tropisetron, and metoclopramide, with RR 1.84 (95% CI 0.41 to 8.33), RR 2.52 (95% CI 0.21 to 30.54) and RR 2.36 (95% CI 0.42 to 13.14), respectively, showed harm associated with uncertainty compared to placebo. For ramosetron versus placebo, with RR 0.79 (95% CI 0.43 to 1.46), and for droperidol versus placebo, with RR 1.05 (95% CI 0.86 to 1.28), the uncertainty of the effect estimates was increased further in the sensitivity analysis compared to the primary network meta-analysis. The estimated value of between-study variance for the sensitivity network meta-analysis of sedation was 0 (tau²) (I^2 = 0%).

Reporting bias (sedation)

Four direct pair-wise comparisons included 10 or more studies for which small-study effects such as reporting or publication bias were investigated: droperidol, metoclopramide, and ondansetron, all compared to placebo; and droperidol compared to ondansetron. Results of the funnel plots, the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. We did not suspect relevant publication bias for any of the comparisons mentioned above. For all comparisons, P values of the arcsine test were > 0.1, and trim and fill sensitivity analyses did not change the conclusions with respect to the range of equivalence.

Subgroup analysis of sedation: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low,

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis of sedation including single drugs only (and excluding combination treatments) with 99 studies and 24 treatments including placebo was conducted. Haloperidol was not included in the network meta-analysis of single drugs for sedation because no other single drug or placebo was a suitable comparator in the corresponding trials. Network geometry, effect estimates, and the ranking order of drugs were similar compared to the primary analysis, including combination prophylaxis. However, ondansetron (RR 0.91, 95% CI 0.81 to 1.01), domperidone (RR 0.92, 95% CI 0.74 to 1.14), and ramosetron (RR 0.92, 95% CI 0.74 to 1.15), each compared to placebo, showed slightly changed treatment effects, changing clinical interpretation of treatment effects from benefit to no or minimal effect with uncertainty. The estimated value of between-study variance for the network meta-analysis of single drugs for sedation was 0.0025 (tau^2) (I^2 = 4.9%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. The following drugs were split into dose categories: aprepitant, dexamethasone, dolasetron, droperidol, granisetron, ondansetron, palonosetron, promethazine, and ramosetron. For amisulpride, dimenhydrinate, methylprednisolone, metoclopramide, perphenazine, and tropisetron, only one dose category was available for subgroup analysis. Drugs without any dose recommendation according to Table 1 (scopolamine) and drugs not of direct interest (benzquinamide, chlorpromazine, cyclizine, dixyrazine, domperidone, amisulpride, thiethylperazine) were included in the analysis and were lumped together, irrespective of the doses being analysed, in the category 'NA'. Rothenberg 1991 and Wagner 1996 and one arm each of Bhatnagar 2007 (granisetron NA) and Turhanoglu 1999 (dimenhydrinate NA) were excluded from the subgroup analysis because they were not associated with one of the three dose categories. The network consisted of 97 studies with 24 treatments split into 36 nodes with dose categories and is presented in the online repository. In the ranking of treatments according to safety, with placebo as the reference compound, high and recommended doses of ondansetron showed benefit with uncertainty, and low doses of ondansetron showed important harm with non-overlapping 95% CIs. In the case of palonosetron, promethazine, or ramosetron, high and recommended doses, respectively, ranked higher than low doses when compared to placebo. However, all 95% CIs between different doses of the same drug overlapped, and the uncertainty of treatment effects was considerable. In the case of dolasetron, droperidol, or granisetron, low and recommended doses, respectively, ranked higher than high doses when compared to placebo. However, all 95% CIs between different doses of the same drug overlapped, and the uncertainty of treatment effects was considerable. Recommended and high doses of aprepitant compared to placebo showed benefit associated with uncertainty. Both recommended and high doses of dexamethasone compared to placebo showed no or minimal effect. For recommended doses of dexamethasone, uncertainty was high.

Sensitivity analysis of sedation: comparability of doses

In 47 (48%) of 97 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis consisted of 12 treatments including placebo. Of the single drugs of direct interest included in the primary network meta-analysis, aprepitant, dimenhydrinate, perphenazine, scopolamine, and tropisetron were not included in the sensitivity analysis due to lack of studies with comparable doses. Treatment effects of three drugs (dolasetron, droperidol, promethazine) were not robust in the sensitivity analysis with placebo as common comparator. Dolasetron (RR 0.68, 95% CI 0.44 to 1.05) compared to placebo showed benefit associated with uncertainty. Droperidol (RR 0.98, 95% CI 0.95 to 1.00) showed no effect, and promethazine (RR 3.76, 95% CI 1.32 to 10.73) showed important harm, both compared to placebo. The estimated value of between-study variance for this sensitivity network meta-analysis of sedation was 0 (tau^2) (I^2 = 0%).

Certainty of evidence: sedation

The certainty of evidence of treatment estimates for sedation evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 6).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for sedation ranged from very low to moderate (Summary of findings 6). Ondansetron (RR 0.87, 95% CI 0.79 to 0.96) probably reduces sedation compared to placebo, with moderate-certainty evidence (imprecision). However, moderate certainty of evidence for ondansetron is restricted to recommended and high doses. Ramosetron (RR 0.89, 95% CI 0.72 to 1.10) and tropisetron (RR 0.74, 95% CI 0.54 to 1.00) may reduce sedation compared to placebo, with low-certainty evidence (study limitations, imprecision). Dolasetron (RR 1.00, 95% CI 0.88 to 1.13) may have little or no effect on sedation compared to placebo, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether granisetron (RR 1.00, 95% CI 0.86 to 1.17) has little or no effect compared to placebo, with very low-certainty evidence (study limitation, very serious concerns for imprecision). We are uncertain whether palonosetron (RR 1.16, 95% CI 0.89 to 1.51) increases sedation compared to placebo, with very low-certainty evidence (study limitation, very serious concerns for imprecision).

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for sedation was assessed as very low to low (Summary of findings 6). Droperidol (RR 0.99, 95% CI 0.96 to 1.01) may have little or no effect on sedation compared to placebo, with low-certainty evidence (very serious concerns for study limitations). Amisulpride (RR 1.00, 95% CI 0.02 to 50.11), with direct evidence only, may have little or no effect on sedation compared to placebo, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether haloperidol (RR 0.95, 95% CI 0.67 to 1.35), with indirect evidence only, and metoclopramide (RR 0.97, 95% CI 0.82 to 1.13), both compared to placebo, have little or no effect on sedation, with very low-certainty evidence (haloperidol: study limitations, incoherence, very serious concerns for imprecision; metoclopramide: study limitations, very serious concerns for imprecision, incoherence). We are uncertain whether perphenazine (RR 0.23, 95% CI 0.03 to 1.73) compared to placebo reduces sedation, with very low-certainty evidence (study limitations, very serious concerns for imprecision).

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

For relevant NK_1 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for sedation was assessed as very low (Summary of findings 6). We are uncertain whether aprepitant (RR 0.43, 95% CI 0.01 to 21.65), with indirect evidence only, reduces sedation compared to placebo, with very low-certainty evidence (incoherence, very serious concerns for imprecision). No studies reporting sedation were available for casopitant, fosaprepitant, and rolapitant.

For relevant corticosteroids (compared to placebo), the certainty of evidence of network effect estimates for sedation was assessed as high to low (Summary of findings 6). Dexamethasone (RR 1.00, 95% CI 0.91 to 1.09) has no effect on sedation compared to placebo, with high-certainty evidence. Methylprednisolone (RR 4.83, 95% CI 0.24 to 98.29), with direct evidence only, may increase sedation compared to placebo, with low-certainty evidence (very serious concerns for imprecision).

For relevant antihistamines (compared to placebo), the certainty of evidence of network effect estimates for sedation was assessed as moderate to very low (Summary of findings 6). Dimenhydrinate (RR 7.66, 95% CI 3.10 to 18.94) probably increases sedation compared to placebo, with moderate-certainty evidence (study limitations). We are uncertain whether promethazine (RR 1.06, 95% CI 0.59 to 1.92) has no or minimal effect on sedation compared to placebo, with very low-certainty evidence (study limitations, very serious concerns for imprecision). No studies reporting sedation were available for meclizine.

We are uncertain whether the anticholinergic scopolamine (RR 1.47, 95% CI 0.79 to 2.72) increases sedation compared to placebo, with very low-certainty evidence (study limitations, very serious concerns for imprecision) (Summary of findings 6).

Extrapyramidal symptoms within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of extrapyramidal symptoms

Pairwise meta-analyses for extrapyramidal symptoms comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for amisulpride (Analysis 1.6), dexamethasone (Analysis 3.6), dolasetron (Analysis 5.6), droperidol (Analysis 6.6), granisetron (Analysis 7.6), haloperidol (Analysis 8.3), metoclopramide (Analysis 10.5), ondansetron (Analysis 11.6), palonosetron (Analysis 12.6), perphenazine (Analysis 13.2), and tropisetron (Analysis 18.6). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

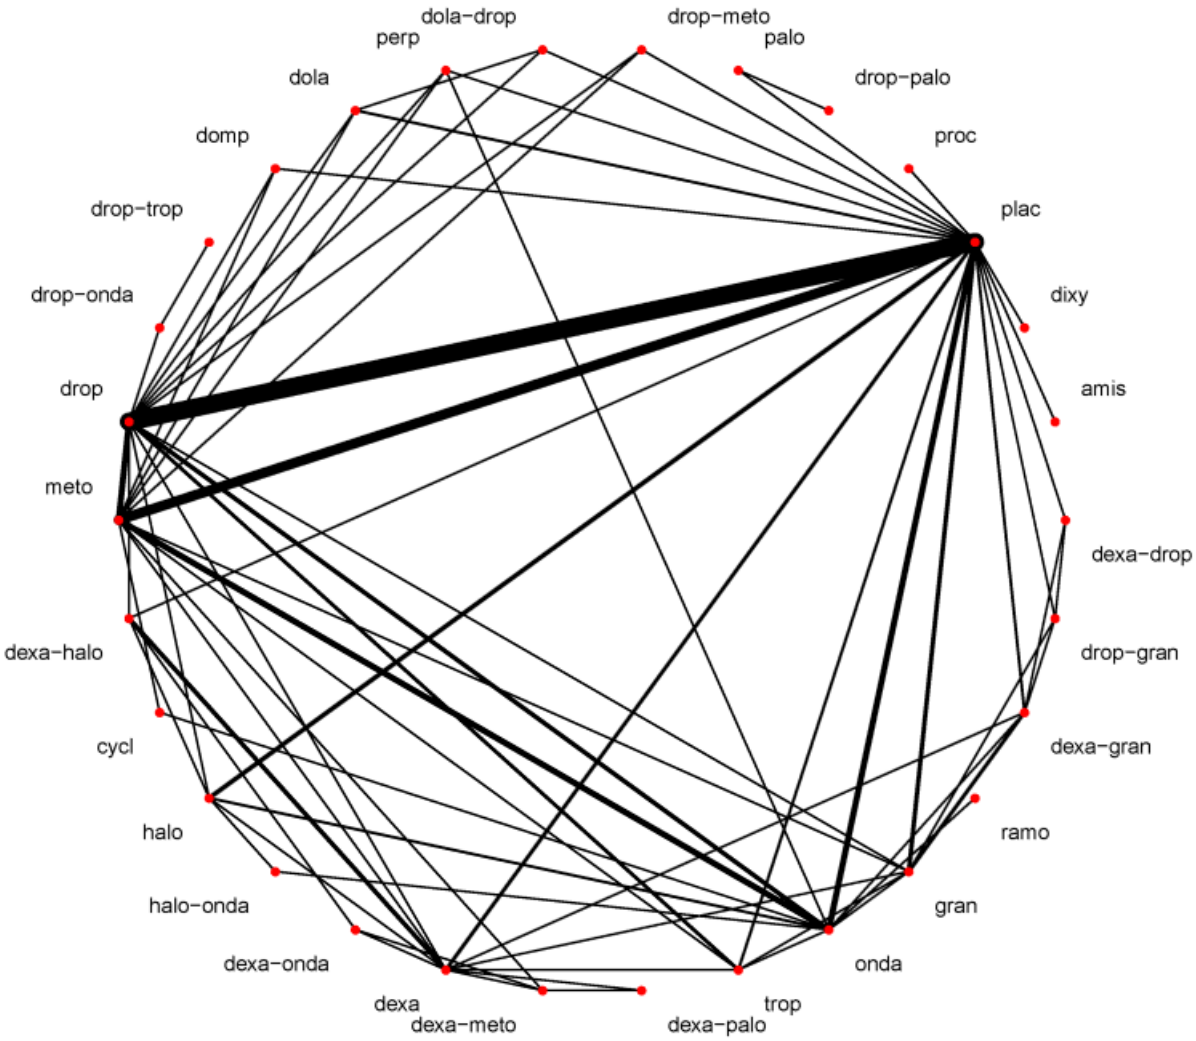
Primary analysis of extrapyramidal symptoms: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome extrapyramidal symptoms are available in an online repository (Supplementary Files-6-extrapyramidal symptoms; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).

In total, 64 studies with 172 pair-wise comparisons due to multi-arm studies and 10,724 participants were eligible for the network meta-analysis of extrapyramidal symptoms. Forty-eight studies (75%) have reported zero events in all study arms. The network included 30 treatments (nodes), with 13 drug combinations, 16 single drugs, and 1 placebo or no treatment (Figure 18). The most common comparisons were droperidol (k = 22 studies) and metoclopramide (k = 12) compared to placebo. Of the single drugs of direct interest, amisulpride and palonosetron were poorly connected to the network, with placebo as the only comparator.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Figure 18. Network geometry of eligible comparisons for postoperative extrapyramidal symptoms. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



For 30 different treatments, 435 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 65 of 435 comparisons, direct and indirect evidence was available, whereas for eight comparisons, only direct evidence was available, and for 362 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (risk ratio, RR) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 19. In terms of extrapyramidal symptoms, none of the 16 single drugs showed important benefit (95% CI upper boundary < 0.9) or important harm (95% CI lower boundary > 1.11) compared to placebo. Six single treatments showed benefit (ondansetron, dexamethasone, dolasetron, tropisetron, ramosetron, granisetron), another six treatments showed no or minimal effect (cyclizine, palonosetron, amisulpride, prochlorperazine, dixyrazine, perphenazine), four treatments showed harm (metoclopramide, haloperidol, droperidol, domperidone), and all treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs ranged between RR 0.73 (95% CI 0.39 to 1.38) for ondansetron and RR 2.05 (95% CI 0.79 to 5.31) for domperidone. None of the combination treatments showed

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

important benefit or important harm compared to placebo. Six combination treatments showed benefit, five showed no or minimal effect, two showed harm, and all treatment effects were associated with uncertainty. Treatment effects of combination treatments ranged between RR 0.42 (95% CI 0.07 to 2.68) for dexamethasone-haloperidol and RR 1.99 (95% CI 0.01 to 490.88) for droperidol-palonosetron.

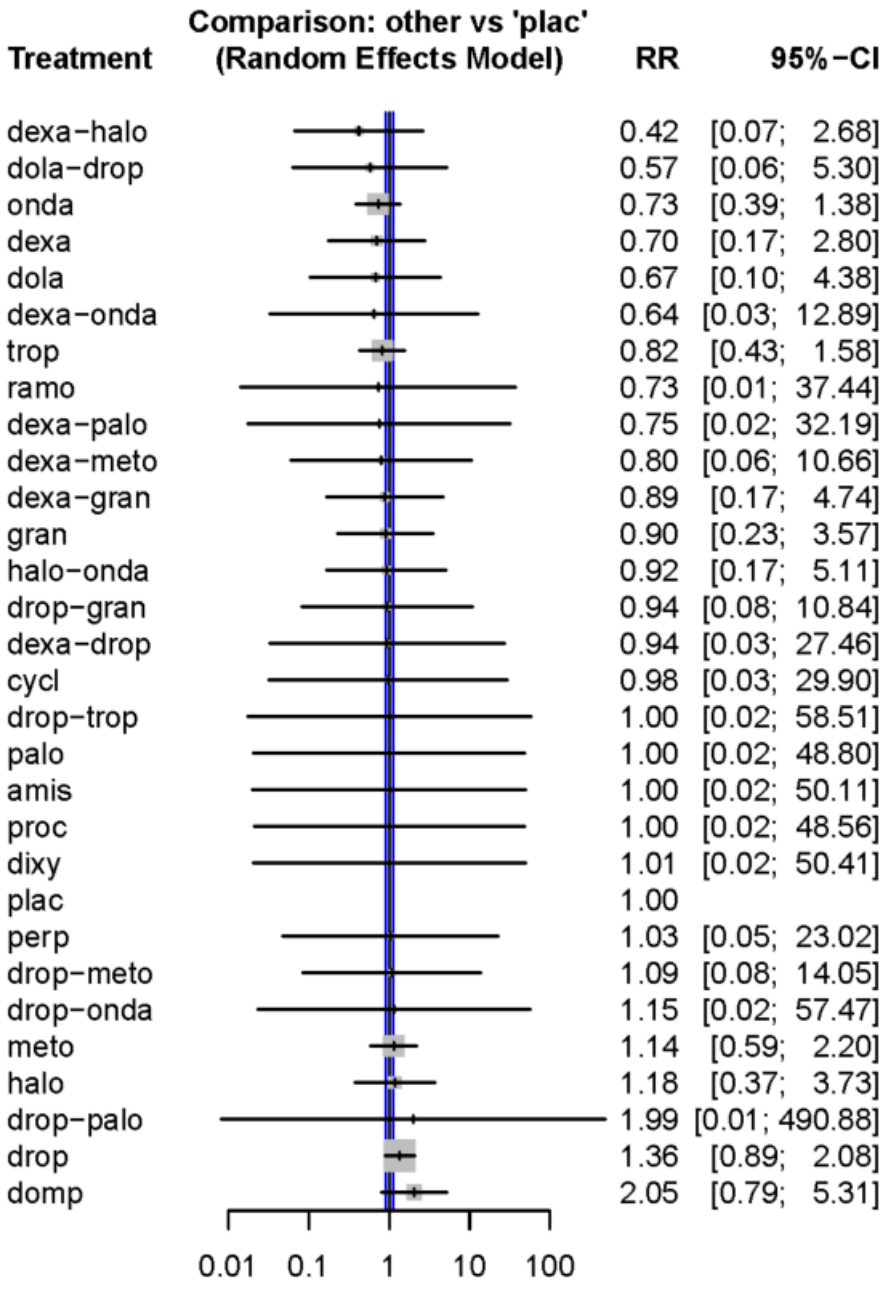
Figure 19. Forest plot of network meta-analysis of all trials for postoperative extrapyramidal symptoms. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to 1.11). Treatments are ranked according to safety based on P scores. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



The estimated value of between-study variance for the network meta-analysis of extrapyramidal symptoms was 0 (tau^2) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 6.86, df = 20, P = 1.00) and no inconsistency between designs (Q = 9.34, df = 58, P = 1.00). No clinically relevant heterogeneity for relevant comparisons (single drugs of

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

direct interest compared to placebo) was detectable because 95% CIs and 95% PIs were compatible with respect to the range of equivalence. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed no disagreement (direct versus indirect) for all 65 comparisons. There was no clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo.

Sensitivity analyses of extrapyramidal symptoms

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of extrapyramidal symptoms: risk of bias

Fifteen (23%) of 64 studies were rated as having high risk of overall bias, 33 (52%) as unclear, and 16 (25%) as low. One study with low risk of bias was not connected to the network of low risk of bias studies and was excluded from the sensitivity analysis (Hu 2017; comparison: droperidol-palonosetron versus palonosetron). The network geometry of the remaining 15 studies at low risk of bias included 15 treatments. Five treatments were two-fold combinations of antiemetic drugs, nine were single drugs, and one was placebo. Of the single drugs of direct interest included in the primary network meta-analysis for extrapyramidal symptoms, palonosetron, perphenazine, ramosetron, and tropisetron were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Comparison of treatment effects of the sensitivity analysis for risk of bias and the primary network meta-analysis for extrapyramidal symptoms with placebo as common comparator revealed robust treatment effects for all single drugs of direct interest except for ondansetron and granisetron. Ondansetron compared to placebo, with RR 1.10 (95% CI 0.32 to 3.79), and granisetron compared to placebo, with RR 1.00 (95% CI 0.02 to 48.80), showed no or minimal effect associated with uncertainty. The estimated value of between-study variance for the sensitivity network meta-analysis of extrapyramidal symptoms was 0 (tau^2) (I^2 = 0%).

Reporting bias (extrapyramidal symptoms)

Two direct pair-wise comparisons included 10 or more studies for which small-study effects such as reporting or publication bias were investigated (droperidol and metoclopramide compared to placebo). Results of the funnel plots, the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. We did not suspect relevant publication bias for any of the comparisons mentioned above. For all comparisons, P values of the arcsine test were > 0.1, and trim and fill sensitivity analyses did not change the conclusions with respect to the range of equivalence.

Subgroup analysis of extrapyramidal symptoms: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis for extrapyramidal symptoms including single drugs only (and excluding combination treatments) with 50 studies and 17 treatments including placebo was conducted. Network geometry, effect estimates, and the ranking order of drugs, with placebo as the reference compound, were robust compared to the primary analysis including combination prophylaxis. The estimated value of between-study variance for the network meta-analysis of single drugs for extrapyramidal symptoms was 0 (tau^2) (I^2 = 0%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. The following drugs were split into dose categories: dexamethasone, droperidol, haloperidol, and ondansetron. For amisulpride, dolasetron, granisetron, metoclopramide, palonosetron, perphenazine, ramosetron, and tropisetron, only one dose category was available for subgroup analysis. Drugs not of direct interest were included in the analysis and were lumped together, irrespective of the doses being analysed, in the category 'NA' (cyclizine, dixyrazine, domperidone, prochlorperazine). Mathia 1988 was excluded from the subgroup analysis because the intervention was not associated with one of the three dose categories (metoclopramide 'NA'). The network consisted of 49 studies with 17 treatments including placebo split into 23 nodes with dose categories and is presented in the online repository. In the ranking of treatments according to safety with placebo as the reference compound, all 95% CIs between different doses of the same drug overlapped, and the uncertainty of treatment effects was considerable. High and recommended doses of ondansetron compared to placebo ranked higher than low doses. Low and recommended doses of droperidol compared to placebo showed harm associated with uncertainty, and high doses showed benefit associated with uncertainty. For both dexamethasone and haloperidol, recommended doses ranked higher than high doses. All treatment effects were associated with uncertainty.

Sensitivity analysis of extrapyramidal symptoms: comparability of doses

In 24 (48%) of 50 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis consisted of 11 treatments including placebo. Of the single drugs of direct interest included in the primary network meta-analysis, perphenazine and tropisetron were not included in the sensitivity analysis due to lack of studies with comparable doses. Treatment effects of six single drugs of direct interest (dolasetron, granisetron, metoclopramide, ondansetron, ramosetron, droperidol) were not robust in the sensitivity analysis with placebo as the reference compound. Dolasetron (RR 0.94, 95% CI 0.09 to 9.52), granisetron (RR 1.01, 95% CI 0.13 to 7.97), metoclopramide (RR 1.00, 95% CI 0.02 to 47.28), ondansetron (RR 1.04, 95% CI 0.07 to 16.44), and ramosetron (RR 1.04, 95% CI 0.01 to 122.62), all compared to placebo, showed no or minimal effects associated with uncertainty. Droperidol compared to placebo showed important harm, with RR 2.78 (95% CI 1.15 to 6.73). The estimated value of between-study variance for this sensitivity network meta-analysis of extrapyramidal symptoms was 0 (tau^2) (I^2 = 0%).

Certainty of evidence: extrapyramidal symptoms

The certainty of evidence of treatment estimates for extrapyramidal symptoms evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 7).

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for extrapyramidal symptoms ranged from very low to low (Summary of findings 7). Dolasetron (RR 0.67; 95% CI 0.10 to 4.38) may reduce extrapyramidal symptoms compared to placebo, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether ondansetron (RR 0.73, 95% CI 0.39 to 1.38) and granisetron (RR 0.90, 95% CI 0.23 to 3.57) reduce extrapyramidal symptoms compared to placebo, with very low-certainty evidence (study limitation, very serious concerns for imprecision). We are uncertain whether ramosetron (RR 0.73, 95% CI 0.01 to 37.44), with indirect evidence only, reduces extrapyramidal symptoms compared to placebo, with very low-certainty evidence (study limitation, incoherence, very serious concerns for imprecision). We are also uncertain whether tropisetron (RR 0.82, 95% CI 0.43 to 1.58) reduces extrapyramidal symptoms compared to placebo, with very low-certainty evidence (very serious concerns for study limitations and imprecision). We are uncertain whether palonosetron (RR 1.00, 95% CI 0.02 to 48.80), with direct evidence only, has little or no effect on extrapyramidal symptoms compared to placebo, with very low-certainty evidence (study limitation, very serious concerns for imprecision).

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for extrapyramidal symptoms was assessed as very low and low (Summary of findings 7). Droperidol (RR 1.36, 95% CI 0.89 to 2.08), haloperidol (RR 1.18, 95% CI 0.37 to 3.73), and metoclopramide (RR 1.14, 95% CI 0.59 to 2.20) may increase extrapyramidal symptoms compared to placebo, with low-certainty evidence (very serious concerns for imprecision). Amisulpride (RR 1.00, 95% CI 0.02 to 50.11), with direct evidence only, may have little or no effect on extrapyramidal symptoms compared to placebo, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether perphenazine (RR 1.03, 95% CI 0.05 to 23.02) compared to placebo has little or no effect on extrapyramidal symptoms, with very low-certainty evidence (study limitations, very serious concerns for imprecision).

No studies reporting extrapyramidal symptoms were available for relevant NK_1 receptor antagonists (compared to placebo) (Summary of findings 7).

For relevant corticosteroids (compared to placebo), the certainty of evidence of network effect estimates for extrapyramidal symptoms was assessed as low for dexamethasone (Summary of findings 7). Dexamethasone (RR 0.70, 95% CI 0.17 to 2.80) may reduce extrapyramidal symptoms compared to placebo, with low-certainty evidence (very serious concerns for imprecision).

No studies reporting extrapyramidal symptoms were available for methylprednisolone.

No studies reporting extrapyramidal symptoms were available for relevant antihistamines (compared to placebo) (Summary of findings 7).

No studies reporting extrapyramidal symptoms were available for the anticholinergic scopolamine (Summary of findings 7).

Constipation within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of constipation

Pairwise meta-analyses of constipation comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for amisulpride (Analysis 1.7), dexamethasone (Analysis 3.7), granisetron (Analysis 7.7), metoclopramide (Analysis 10.6), ondansetron (Analysis 11.7), palonosetron (Analysis 12.7), ramosetron (Analysis 15.6), and tropisetron (Analysis 18.7). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

Primary analysis of constipation: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome constipation are available in an online repository (Supplementary Files-7-constipation*; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).*

In total, 44 RCTs including 11,540 participants were eligible for the network meta-analysis of constipation. Six studies (14%) have reported zero events in all study arms. One study was not connected to the network and was excluded from the following analysis: Awad 2002; comparison: droperidol-ondansetron versus droperidol. The network geometry of the remaining 43 studies with 74 pair-wise comparisons due to multi-arm studies included 23 different treatments (nodes) (Figure 20). The 23 treatments included 10 drug combinations, 12 single drugs, and placebo or no treatment. The most common comparisons were ondansetron (k = 8 studies), dexamethasone (k = 3), dexamethasone-granisetron (k = 3), granisetron (k = 3), and palonosetron (k = 3), all compared to placebo; casopitant-ondansetron (k = 4) and aprepitant (k = 3) compared to ondansetron; and ondansetron compared to palonosetron (k = 3). Of the single drugs of direct interest, amisulpride was poorly connected to the network, with placebo as the only comparator.

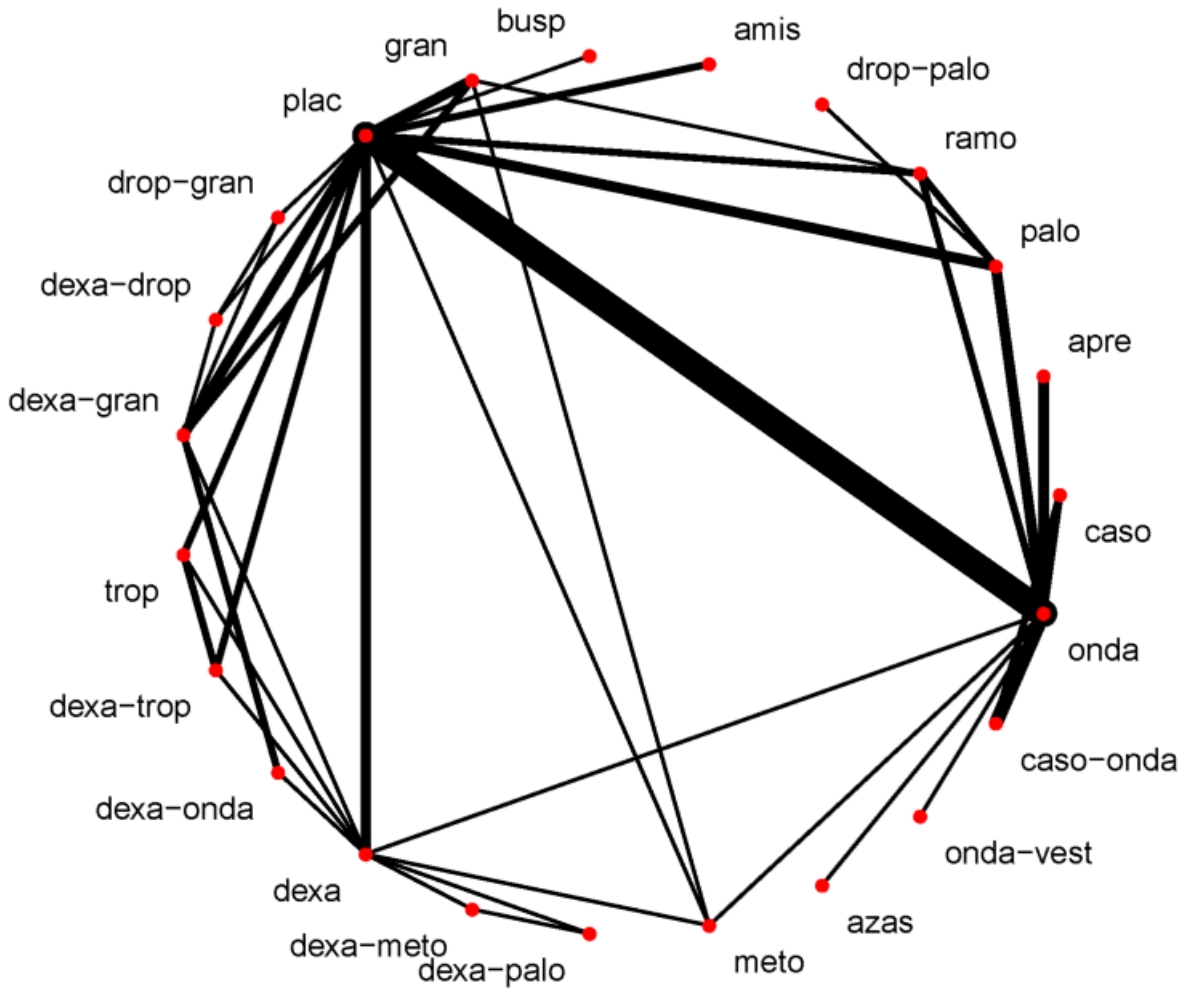
Figure 20. Network geometry of eligible comparisons for postoperative constipation. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



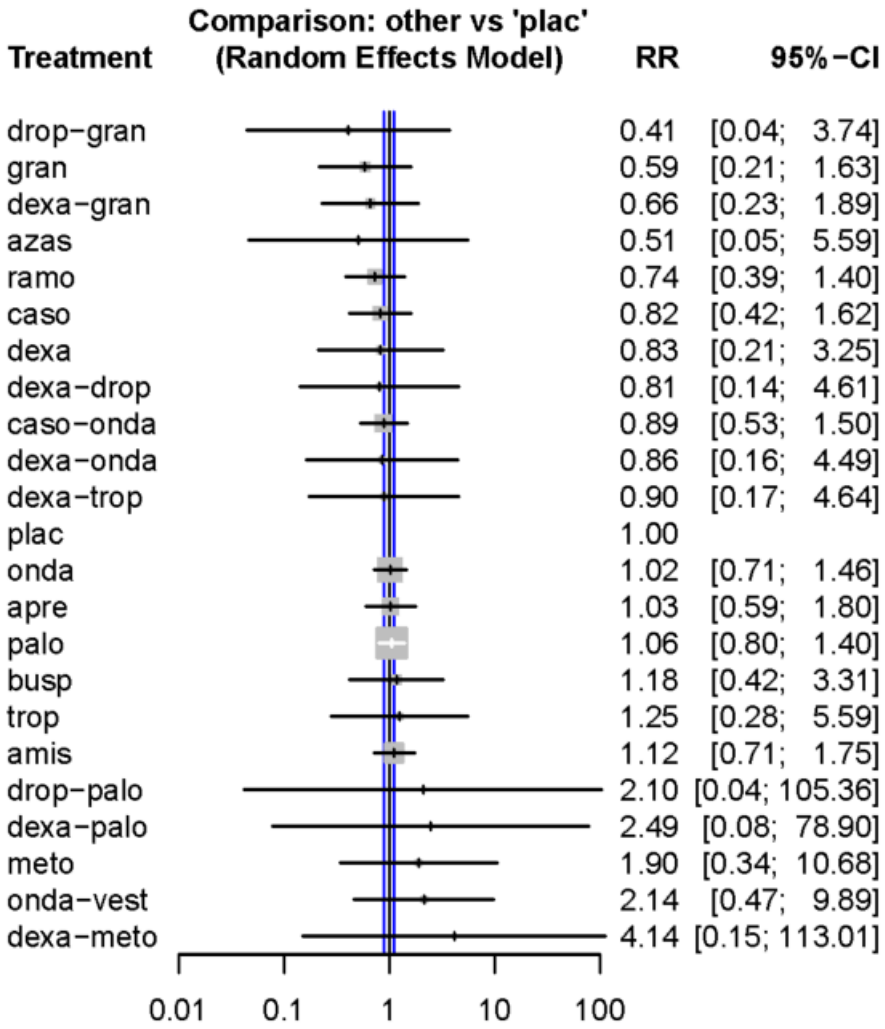
For 253 different treatments, 253 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 30 of 253 comparisons, direct and indirect evidence was available, whereas for 11 comparisons, only direct evidence was available, and for 212 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (risk ratio, RR) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 21. In terms of constipation, none of the 12 single drugs showed important benefit (95% CI upper boundary < 0.9) or important harm (95% CI lower boundary > 1.11) compared to placebo. Five single treatments showed benefit (granisetron, azasetron, ramosetron, casopitant, dexamethasone), three treatments showed no or minimal effect (ondansetron, aprepitant, palonosetron), four treatments showed harm (buspirone, tropisetron, amisulpride, metoclopramide), and all treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs ranged between RR 0.59 (95% CI 0.21 to 1.63) for granisetron and RR 1.90 (95% CI 0.34 to 10.68) for metoclopramide. None of the combination treatments showed important benefit or important harm compared to placebo. Six combination treatments

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

showed benefit, four showed harm, and all treatment effects were associated with uncertainty. Treatment effects of combination treatments ranged between RR 0.41 (95% CI 0.04 to 3.74) for droperidol-granisetron and RR 4.14 (95% CI 0.15 to 113.01) for dexamethasone-metoclopramide.

Figure 21. Forest plot of network meta-analysis of all trials for postoperative constipation. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to 1.11). Treatments are ranked according to safety based on P scores. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



The estimated value of between-study variance for the network meta-analysis of constipation was 0 (tau^2) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 7.68, df = 20, P = 0.99) and no inconsistency between designs (Q = 14.43, df = 15, P = 0.49). No clinically relevant heterogeneity for relevant comparisons (single drugs of direct interest compared to placebo) was detectable because 95% CIs and 95% PIs were compatible with respect to the range of equivalence. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed disagreement (direct versus indirect) for two out of 30 comparisons, namely, casopitant versus ondansetron (P = 0.0006) and casopitant-ondansetron versus casopitant (P = 0.0006). There was no clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo.

Sensitivity analyses of constipation

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of constipation: risk of bias

Five (12%) of 43 studies were rated as having high risk of overall bias, 23 (53%) as unclear, and 15 (35%) as low. Two studies with low

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

risk of bias were not connected to the network of low risk of bias studies and were excluded from the sensitivity analysis (Hu 2017, comparison: droperidol-palonosetron versus palonosetron; Park 2013, comparison: ramosetron versus palonosetron). The network geometry of the remaining 13 studies at low risk of bias included 13 treatments. Three treatments were two-fold combinations of antiemetic drugs, nine were single drugs, and one was placebo. Of the single drugs of direct interest included in the primary network meta-analysis for constipation, palonosetron, ramosetron, and tropisetron were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Comparison of treatment effects of the sensitivity analysis for risk of bias and the primary network meta-analysis for constipation with placebo as the reference compound revealed non-robust treatment effects for five single drugs of direct interest (granisetron, casopitant, amisulpride, aprepitant, ondansetron). Granisetron, casopitant, and amisulpride, with RR 1.00 (95% CI 0.02 to 49.06), RR 1.09 (95% CI 0.18 to 6.52), and RR 1.11 (95% CI 0.60 to 2.02), respectively, showed no or minimal effect associated with uncertainty. Aprepitant and ondansetron, with RR 1.34 (95% CI 0.26 to 6.79) and RR 1.37 (95% CI 0.30 to 6.19), respectively, showed harm associated with uncertainty. The estimated value of between-study variance for the sensitivity network meta-analysis of constipation was 0.0743 (tau^2) (I^2 = 22.2%).

Reporting bias (constipation)

None of the direct pair-wise comparisons included 10 or more studies. Therefore, analyses investigating reporting or publication bias were not performed.

Subgroup analysis of constipation: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis for constipation including single drugs only (and excluding combination treatments) with 35 studies and 13 treatments including placebo was conducted. Network geometry, effect estimates, and the ranking order of drugs with placebo as reference compound were robust compared to the primary analysis including combination prophylaxis. The estimated value of between-study variance for the network meta-analysis of single drugs for constipation was 0 (tau^2) (I^2 = 0%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. The following drugs were split into dose categories: amisulpride, aprepitant, dexamethasone, ondansetron, palonosetron, and ramosetron. For casopitant, granisetron, metoclopramide, and tropisetron, only one dose category was available for subgroup analysis. Drugs not of direct interest were included in the analysis and were lumped together, irrespective of the doses being analysed, in the category 'NA' (azasetron, buspirone). Eberhart 2006 was excluded from the subgroup analysis because the interventions were not associated with one of the three dose categories (dexamethasone 'NA', droperidol 'NA'). The network consisted of 34 studies with 13 treatments including placebo split into 23 nodes with dose categories and is presented in the online repository. In the ranking of treatments according to safety with placebo as reference compound, all 95% CIs between different doses of the same drug overlapped, and the uncertainty of treatment effects was considerable. High doses of aprepitant, dexamethasone, and palonosetron compared to placebo ranked higher than recommended and low doses of the same drug. High and recommended doses of ondansetron compared to placebo ranked higher than low doses. High and low doses of amisulpride compared to placebo ranked higher than recommended doses. Recommended doses of ramosetron compared to placebo ranked higher than high and low doses. All of the above mentioned treatment effects were associated with uncertainty.

Sensitivity analysis of constipation: comparability of doses

In 24 (69%) of 35 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis consisted of nine treatments including placebo. Of the single drugs of direct interest included in the primary network meta-analysis, aprepitant and metoclopramide were not included in the sensitivity analysis due to lack of studies with comparable doses. Treatment effects of two single drugs of direct interest (dexamethasone, tropisetron) were not robust in the sensitivity analysis with placebo as reference compound. Dexamethasone (RR 1.00, 95% CI 0.02 to 49.39) and tropisetron (RR 1.00, 95% CI 0.02 to 49.02) compared to placebo showed no or minimal effect associated with uncertainty. The estimated value of between-study variance for this sensitivity network meta-analysis of constipation was 0 (tau^2) (I^2 = 0%).

Certainty of evidence: constipation

The certainty of evidence of treatment estimates for constipation evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 8).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for constipation was assessed as very low (Summary of findings 8). The certainty of evidence of network effect estimates was downgraded due to study limitations and very serious concerns for imprecision. We are uncertain whether granisetron (RR 0.59, 95% CI 0.21 to 1.63) and ramosetron (RR 0.74, 95% CI 0.39 to 1.40) compared to placebo reduce constipation. We are uncertain whether ondansetron (RR 1.02, 95% CI 0.71 to 1.46) and palonosetron (RR 1.06, 95% CI 0.80 to 1.40) compared to placebo have little or no effect on constipation. We are also uncertain whether tropisetron (RR 1.25, 95% CI 0.28 to 5.59) compared to placebo increases constipation. No studies reporting constipation were available for dolasetron.

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for constipation was assessed as very low and low (Summary of findings 8). Metoclopramide (RR 1.90, 95% CI 0.34 to 10.68) compared to placebo may increase constipation, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether amisulpride (RR 1.12, 95% CI 0.71 to 1.75) compared to placebo, with direct evidence only, increases constipation, with very low-certainty evidence (study limitations, very serious concerns for imprecision). No studies reporting constipation were available for droperidol, haloperidol, and perphenazine.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

For relevant NK_1 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for constipation was assessed as very low (Summary of findings 8). We are uncertain whether casopitant (RR 0.82, 95% CI 0.42 to 1.62) compared to placebo reduces constipation, with very low-certainty evidence (study limitations, incoherence, very serious concerns for imprecision). We are uncertain whether aprepitant (RR 1.03, 95% CI 0.59 to 1.80) compared to placebo has little or no effect on constipation, with very low-certainty evidence (study limitations, incoherence, very serious concerns for imprecision). For both aprepitant and casopitant, only indirect evidence was available. No studies reporting constipation were available for fosaprepitant and rolapitant.

For relevant corticosteroids (compared to placebo), the certainty of evidence of network effect estimates for constipation was assessed as low for dexamethasone (Summary of findings 8). Dexamethasone (RR 0.83, 95% CI 0.21 to 3.25) compared to placebo may reduce constipation, with low-certainty evidence (very serious concerns for imprecision). No studies reporting constipation were available for methylprednisolone.

No studies reporting constipation were available for relevant antihistamines (compared to placebo) (Summary of findings 8).

No studies reporting constipation were available for the anticholinergic scopolamine (Summary of findings 8).

Wound infection within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of wound infection

Pairwise meta-analyses for wound infection comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for dexamethasone (Analysis 3.8), methylprednisolone (Analysis 9.2), metoclopramide (Analysis 10.7), and tropisetron (Analysis 18.8). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

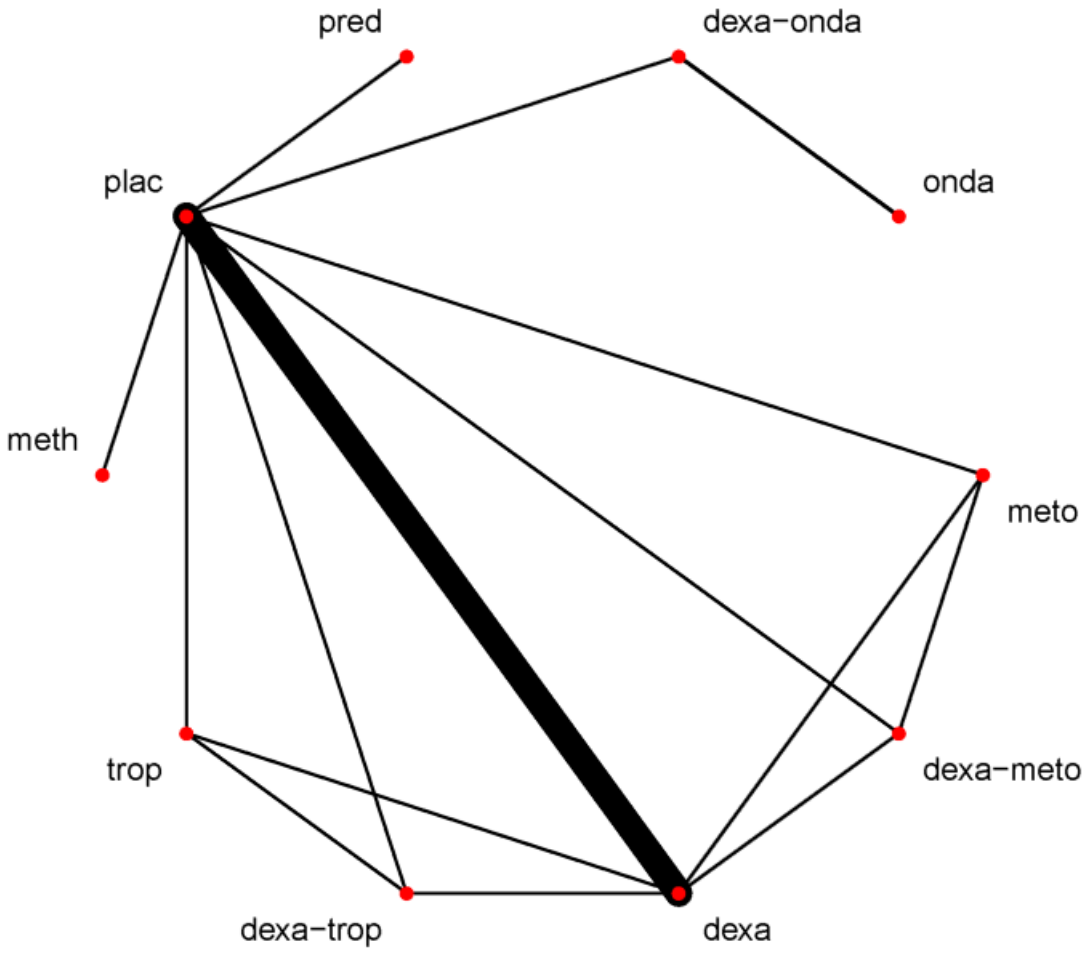
Primary analysis of wound infection: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome wound infection are available in an online repository (Supplementary Files-8-wound infection ; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).

In total, 35 RCTs including 4531 participants were eligible for the network meta-analysis of wound infection. Twenty-eight studies (80%) have reported zero events in all study arms. Three studies were not connected to the network and were excluded from the following analyses: Baxendale 1993, comparison: dexamethasone-scopolamine versus scopolamine; Corcoran 2017, comparison: dexamethasone-granisetron versus granisetron; Eberhart 2011, comparison: dexamethasone-dolasetron versus dolasetron. The network geometry of the remaining 32 studies with 44 pair-wise comparisons due to multi-arm studies included 10 different treatments (nodes) (Figure 22). The 10 treatments included three drug combinations, six single drugs, and placebo or no treatment. The most common comparison was dexamethasone versus placebo (k = 24). Of the single drugs of direct interest, methylprednisolone was poorly connected to the network, with placebo as the only comparator.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Figure 22. Network geometry of eligible comparisons for wound infection within 7 days postoperatively. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



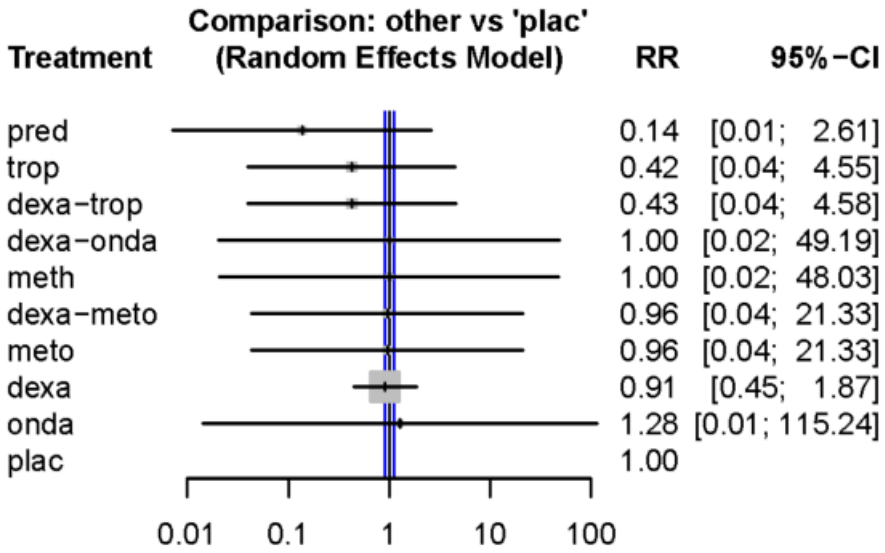
For 10 different treatments, 45 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For nine of 45 comparisons, direct and indirect evidence was available, whereas for six comparisons, only direct evidence was available, and for 30 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (risk ratio, RR) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 23. In terms of wound infection, none of the six single drugs showed important benefit (95% CI upper boundary < 0.9) or important harm (95% CI lower boundary > 1.11) compared to placebo. Two single treatments showed benefit (prednisolone, tropisetron), three treatments showed no or minimal effect (methylprednisolone, metoclopramide, dexamethasone), one treatment showed harm (ondansetron), and all treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs ranged between RR 0.14 (95% CI 0.01 to 2.61) for prednisolone and RR 1.28 (95% CI 0.01 to 115.24) for ondansetron. None of the combination treatments showed important benefit or important harm compared to placebo. One combination treatment showed benefit, two showed no or minimal effect, and all treatment

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

effects were associated with uncertainty. Treatment effects of combination treatments ranged between RR 0.43 (95% CI 0.04 to 4.58) for dexamethasone-tropisetron and RR 0.96 (95% CI 0.04 to 21.33) for dexamethasone-metoclopramide.

Figure 23. Forest plot of network meta-analysis of all trials for wound infection within 7 days postoperatively. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to 1.11). Treatments are ranked according to safety based on P scores. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



The estimated value of between-study variance for the network meta-analysis of wound infection was 0 (tau^2) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 3.5, df = 23, P = 1.00) and no inconsistency between designs (Q = 0.29, df = 5, P = 1.00). No clinically relevant heterogeneity for relevant comparisons (single drugs of direct interest compared to placebo) was detectable because 95% CIs and 95% PIs were compatible with respect to the range of equivalence. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed no disagreement (direct versus indirect) for any of the nine comparisons. There was no clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo.

Sensitivity analyses of wound infection

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of wound infection: risk of bias

Two (6%) of 32 studies were rated as having high risk of overall bias, 12 (38%) as unclear, and 18 (56%) as low. One study with low risk of bias was not connected to the network of low risk of bias studies and was excluded from the sensitivity analysis (Ko Iam 2015, comparison: dexamethasone-metoclopramide versus metoclopramide). The network geometry of the remaining 17 studies at low risk of bias included seven treatments. Two treatments were two-fold combinations of antiemetic drugs, four were single drugs, and one was placebo. Of the single drugs of direct interest included in the primary network meta-analysis for wound infection, methylprednisolone and metoclopramide were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Comparison of treatment effects of the sensitivity analysis for risk of bias and the primary network meta-analysis for wound infection with placebo as the reference compound revealed a non-robust treatment effect for dexamethasone. Dexamethasone compared to placebo, with RR 0.69 (95% CI 0.26 to 1.84), showed benefit associated with uncertainty. The estimated value of between-study variance for the sensitivity network meta-analysis of wound infection was 0 (tau^2) (I^2 = 0%).

Reporting bias (wound infection)

One direct pair-wise comparison included 10 or more studies for which small-study effects such as reporting or publication bias were investigated (dexamethasone versus placebo). Results of the funnel plot, the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. We did not suspect relevant publication bias for this comparison (P = 0.22).

Subgroup analysis of wound infection: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis for wound infection including single drugs only (and excluding combination treatments), with 27 studies and 6 treatments including placebo, was conducted. Ondansetron was not included in the network meta-analysis of single drugs for wound infection because no other single drug or placebo was a suitable comparator in the corresponding trials. Network geometry, effect estimates, and the ranking order of the remaining drugs were similar compared to the primary analysis including combination prophylaxis. The estimated value of between-study variance for the network meta-analysis of single drugs for wound infection was 0 (tau^2) (I^2 = 0%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. The only drug that was split into dose categories was dexamethasone. For metoclopramide and tropisetron, only one dose category was available for subgroup analysis. Drugs not of direct interest were included in the analysis and were lumped together, irrespective of the doses being analysed, in the category 'NA' (prednisolone). Methylprednisolone, reported in only one study (Kizilkaya 2004), was attributed to dose category 'NA' due to an unusual route of application (intraarticular). Two studies were excluded from the subgroup analysis because the interventions were not associated with one of the three dose categories (dexamethasone 'NA', tropisetron 'NA') (Eberhart 2006; Hefni 2014). The network consisted of 25 studies with six treatments including placebo split into eight nodes with dose categories and is presented in the online repository. Low doses of dexamethasone compared to placebo ranked higher than recommended and high doses. However, all 95% CIs between different doses of dexamethasone overlapped, and the uncertainty of treatment effects was considerable.

Sensitivity analysis of wound infection: comparability of doses

In 22 (88%) of 25 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis consisted of dexamethasone, tropisetron, and placebo. Of the single drugs of direct interest included in the primary network meta-analysis, metoclopramide and methylprednisolone were not included in the sensitivity analysis due to lack of studies with comparable doses. The treatment estimate for dexamethasone was robust in the sensitivity analysis with placebo as reference compound, and the estimate for tropisetron was not robust. Tropisetron (RR 0.96, 95% CI 0.02 to 51.15) compared to placebo showed no or minimal effect associated with uncertainty. The estimated value of between-study variance for this sensitivity network meta-analysis of wound infection was 0 (tau^2) (I^2 = 0%).

Certainty of evidence: wound infection

The certainty of evidence of treatment estimates for wound infection evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 9).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for wound infection was assessed as very low to low (Summary of findings 9). Tropisetron (RR 0.42, 95% CI 0.04 to 4.55) compared to placebo may reduce wound infection, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether ondansetron (RR 1.28, 95% CI 0.01 to 115.24) increases wound infection compared to placebo, with indirect evidence only and very low-certainty evidence (incoherence, very serious concerns for imprecision). No studies reporting wound infection were available for dolasetron, granisetron, palonosetron, and ramosetron.

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for wound infection was assessed as very low (Summary of findings 9). We are uncertain whether metoclopramide (RR 0.96, 95% CI 0.04 to 21.33) compared to placebo has little or no effect on wound infection, with very low-certainty evidence (study limitations, very serious concerns for imprecision). No studies reporting wound infection were available for amisulpride, droperidol, haloperidol, and perphenazine.

No studies reporting wound infection were available for relevant NK_1 receptor antagonists (Summary of findings 9).

For relevant corticosteroids (compared to placebo), the certainty of evidence of network effect estimates for wound infection was assessed as very low (Summary of findings 9). We are uncertain whether dexamethasone (RR 0.91, 95% CI 0.45 to 1.87) compared to placebo has little or no effect on wound infection, with very low-certainty evidence (study limitations, very serious concerns for imprecision). We are uncertain whether methylprednisolone (RR 1.00, 95% CI 0.02 to 48.03) compared to placebo, with direct evidence only, has little or no effect on wound infection, with very low-certainty evidence (very serious concerns for study limitations and imprecision).

No studies reporting wound infection were available for relevant antihistamines (Summary of findings 9).

No studies reporting wound infection were available for the anticholinergic scopolamine (Summary of findings 9).

Arrhythmia within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of arrhythmia

Pairwise meta-analyses for arrhythmia comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for dexamethasone Analysis 3.9), dolasetron (Analysis 5.7), droperidol (Analysis 6.7), granisetron (Analysis 7.8), haloperidol (Analysis 8.4), methylprednisolone (Analysis 9.3), metoclopramide (Analysis 10.8), ondansetron (Analysis 11.8), ramosetron (Analysis 15.7), and tropisetron (Analysis 18.9). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

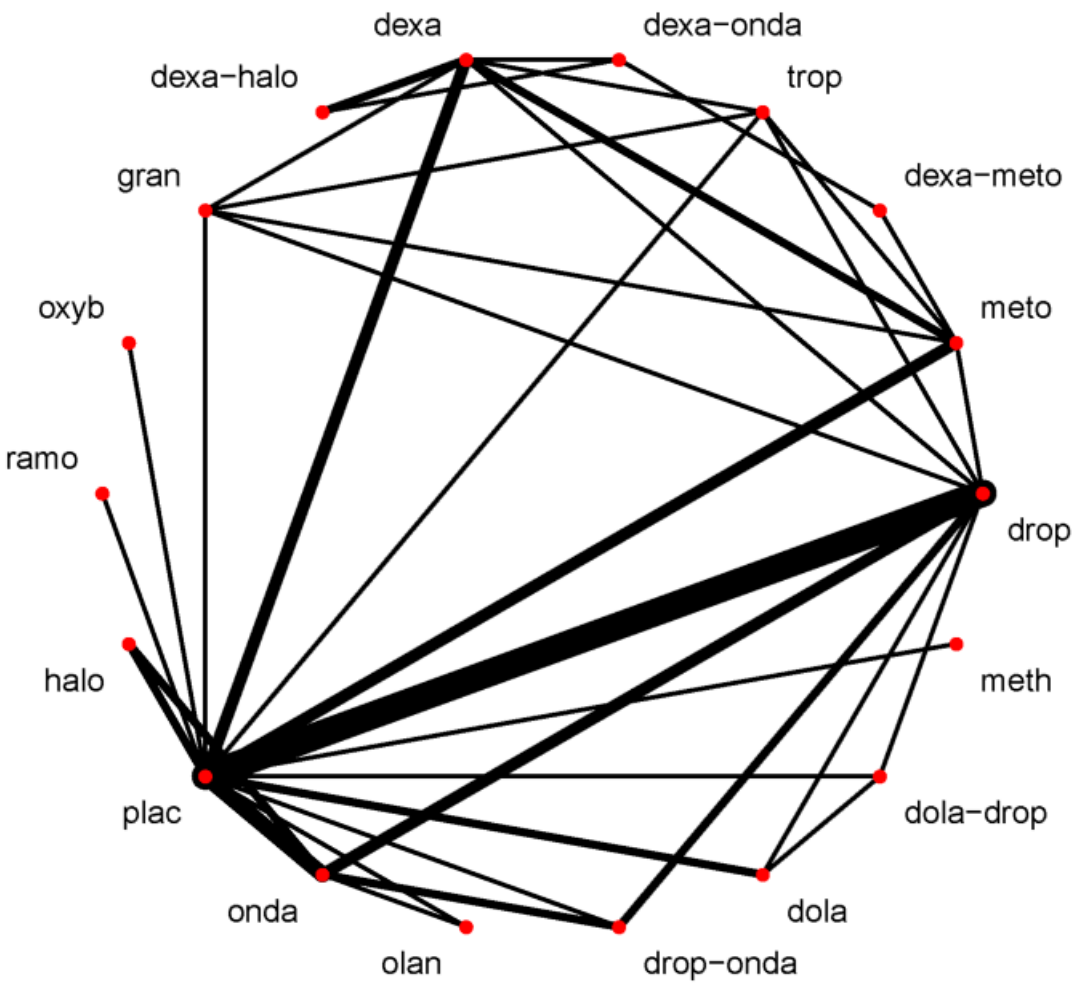
Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Primary analysis of arrhythmia: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome arrhythmia are available in an online repository (Supplementary Files-9-arrhythmia *; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).*

In total, 25 RCTs including 5067 participants were eligible for the network meta-analysis of arrhythmia. Eighteen studies (72%) have reported zero events in all study arms. The network included 18 different treatments (nodes) and consisted of 59 pair-wise comparisons due to multi-arm studies (Figure 24). The 18 treatments included five two-fold drug combinations, 12 single drugs, and placebo or no treatment. The most common comparisons were droperidol (k = 7), ondansetron (k = 4), dexamethasone (k = 3), metoclopramide (k = 3), all compared to placebo, and droperidol compared to ondansetron (k = 3). Of the single drugs of direct interest, methylprednisolone and ramosetron were poorly connected to the network, with placebo as the only comparator.

Figure 24. Network geometry of eligible comparisons for postoperative arrhythmia. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.

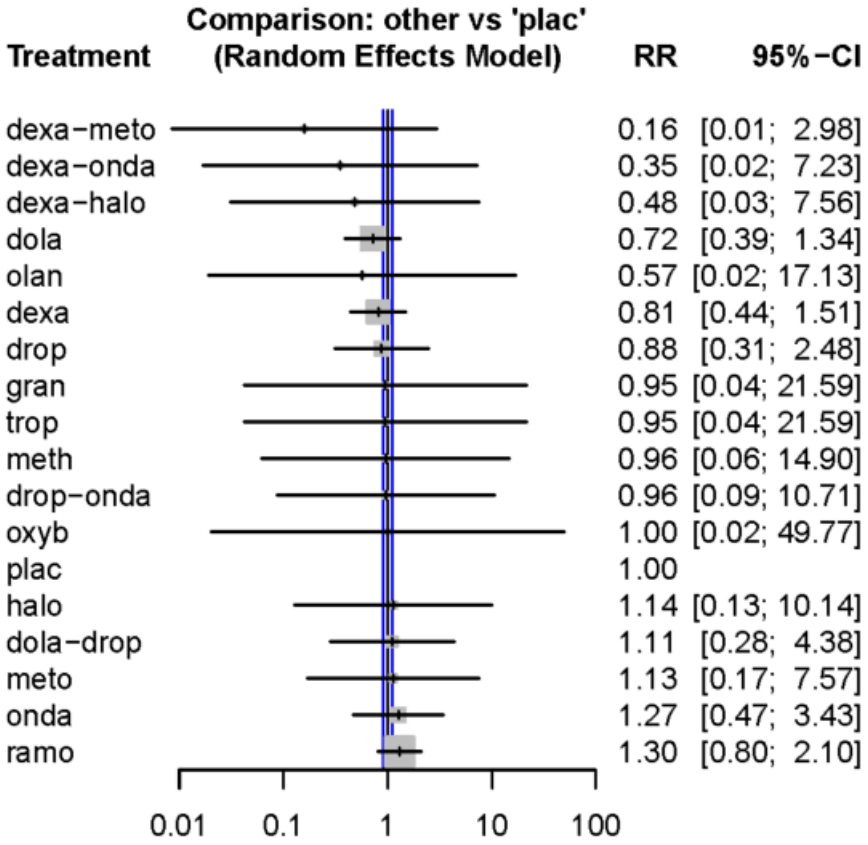


Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

For 18 different treatments, 153 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 33 of 153 comparisons, direct and indirect evidence was available, whereas for four comparisons, only direct evidence was available, and for 116 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (risk ratio, RR) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 25. In terms of arrhythmia, none of the 12 single drugs showed important benefit (95% CI upper boundary < 0.9) or important harm (95% CI lower boundary > 1.11) compared to placebo. Four single treatments showed benefit (dolasetron, olanzapine dexamethasone, droperidol), four showed no or minimal effect (granisetron, tropisetron, methylprednisolone, oxybutynin), four showed harm (haloperidol, metoclopramide, ondansetron, ramosetron), and all treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs ranged between RR 0.72 (95% CI 0.39 to 1.34) for dolasetron and RR 1.30 (95% CI 0.80 to 2.10) for ramosetron. None of the five combination treatments showed important benefit or important harm compared to placebo. Three combination treatments showed benefit, one showed little or no effect, and one showed harm, and all treatment effects were associated with uncertainty. Treatment effects of combination treatments ranged between RR 0.16 (95% CI 0.01 to 2.98) for dexamethasone-metoclopramide and RR 1.11 (95% CI 0.28 to 4.38) for dolasetron-droperidol.

Figure 25. Forest plot of network meta-analysis of all trials for postoperative arrhythmia. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to 1.11). Treatments are ranked according to safety based on P scores. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

The estimated value of between-study variance for the network meta-analysis of arrhythmia was 0 (tau^2) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 0.10, df = 3, P = 0.99) and no inconsistency between designs (Q = 0.78, df = 18, P = 1.00). No clinically relevant heterogeneity for relevant comparisons (single drugs of direct interest compared to placebo) was detectable because 95% CIs and 95% PIs were compatible with respect to the range of equivalence. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed no disagreement (direct versus indirect) for any of the 33 comparisons There was no clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo.

Sensitivity analyses of arrhythmia

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of arrhythmia: risk of bias

Three (12%) of 25 studies were rated as having high risk of overall bias, eight (25%) as unclear, and 14 (56%) as low. One study with low risk of bias was not connected to the network of low risk of bias studies and was excluded from the sensitivity analysis (Ko Iam 2015, comparison: dexamethasone-metoclopramide versus metoclopramide). The network geometry of the remaining 13 studies at low risk of bias included 11 treatments. Three treatments were two-fold combinations of antiemetic drugs, seven were single drugs, and one was placebo. Of the single drugs of direct interest included in the primary network meta-analysis for arrhythmia, granisetron, methylprednisolone, metoclopramide, and tropisetron were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Comparison of treatment effects of the sensitivity analysis for risk of bias and the primary network meta-analysis for arrhythmia with placebo as reference compound revealed non-robust treatment effects for two drugs of direct interest (ondansetron, haloperidol). Haloperidol and ondansetron compared to placebo with RR 0.95 (95% CI 0.05 to 18.64) and RR 0.90 (95% CI 0.10 to 7.88), respectively, showed no or minimal effect associated with uncertainty. The estimated value of between-study variance for the sensitivity network meta-analysis of arrhythmia was 0 (tau^2) (I^2 = 0%).

Reporting bias (arrhythmia)

None of the direct pair-wise comparisons included 10 or more studies. Therefore, analyses investigating reporting or publication bias were not performed.

Subgroup analysis of arrhythmia: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis for arrhythmia including single drugs only (and excluding combination treatments) with 21 studies and 13 treatments including placebo was conducted. Network geometry, effect estimates, and the ranking order of drugs were similar compared to the primary analysis including combination prophylaxis. However, the comparison metoclopramide versus placebo (RR 0.93, 95% CI 0.13 to 6.80) showed a slightly changed treatment effect, changing clinical interpretation from harm to no or minimal effect, both associated with uncertainty. The estimated value of between-study variance for the network meta-analysis of single drugs for arrhythmia was 0 (tau^2) (I^2 = 0%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. The following drugs were split into dose categories: dexamethasone, dolasetron, droperidol, haloperidol, and ondansetron. For granisetron, methylprednisolone, metoclopramide, ramosetron, and tropisetron only one dose category was available for subgroup analysis. Drugs not of direct interest were lumped together, irrespective of the doses being analysed, in the category 'NA' (olanzapine, oxybutynin). The network consisted of 21 studies with 13 treatments including placebo split into 19 nodes with dose categories. In the ranking of treatments according to safety with placebo as the reference compound, recommended doses of ondansetron showed harm associated with uncertainty, with RR 2.88 (95% CI 1.09 to 7.61). Low (RR 0.11, 95% CI 0.01 to 1.99) and high doses (RR 0.23, 95% CI 0.02 to 2.37) of ondansetron showed benefit associated with uncertainty. High doses of dexamethasone ranked higher than recommended doses. All doses of dolasetron showed benefit, all doses of haloperidol showed harm, and all estimates were associated with uncertainty. Overall, the 95% CIs between different doses of all single drugs overlapped, and the uncertainty of treatment effects was considerable, limiting reliable conclusions.

Sensitivity analysis of arrhythmia: comparability of doses

In 15 (71%) of 21 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis consisted of eight treatments including placebo. Of the single drugs of direct interest included in the primary network meta-analysis, granisetron, metoclopramide, and tropisetron were not included in the sensitivity analysis due to lack of studies with comparable doses. Estimated treatment effects for other single drugs of direct interest were robust in the sensitivity analysis with placebo as reference compound, except for haloperidol, with no or little effect associated with uncertainty (RR 1.09, 95% CI 0.08 to 14.13). The estimated value of between-study variance for this sensitivity network meta-analysis of arrhythmia was 0 (tau^2) (I^2 = 0%).

Certainty of evidence: arrhythmia

The certainty of evidence of treatment estimates for arrhythmia evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 10).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for arrhythmia ranged from very low to low (Summary of findings 10). Ramosetron (RR 1.30, 95% CI 0.80 to 2.10), with direct evidence only, may increase and dolasetron (RR 0.72, 95% CI 0.39 to 1.34) may reduce arrhythmia compared to placebo, both with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether ondansetron (RR 1.27, 95% CI 0.47 to 3.43) compared to placebo increases arrhythmia, with very low-certainty evidence (study limitations, very serious concerns for imprecision). We are uncertain whether granisetron (RR 0.95, 95% CI 0.04 to 21.59) and

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

tropisetron (RR 0.95, 95% CI 0.04 to 21.59) compared to placebo have little or no effect on arrhythmia, with very low-certainty evidence (study limitations, very serious concerns for imprecision). No studies reporting arrhythmia were available for palonosetron.

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for arrhythmia was assessed as very low (Summary of findings 10) (study limitations and very serious concerns for imprecision). We are uncertain whether droperidol (RR 0.88, 95% CI 0.31 to 2.48) compared to placebo reduces arrhythmia. We are uncertain whether metoclopramide (RR 1.13, 95% CI 0.17 to 7.57) and haloperidol (RR 1.14, 95% CI 0.13 to 10.14) compared to placebo increase arrhythmia. No studies reporting arrhythmia were available for amisulpride and perphenazine.

No studies reporting arrhythmia were available for relevant NK_1 receptor antagonists (Summary of findings 10).

For relevant corticosteroids (compared to placebo), the certainty of evidence of network effect estimates for arrhythmia was assessed as low and very low (Summary of findings 10). Dexamethasone (RR 0.81, 95% CI 0.44 to 1.51) may reduce arrhythmia compared to placebo, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether methylprednisolone (RR 0.96, 95% CI 0.06 to 14.90) compared to placebo, with direct evidence only, has little or no effect on arrhythmia, with very low-certainty evidence (very serious concerns for study limitations and imprecision).

No studies reporting arrhythmia were available for relevant antihistamines (Summary of findings 10).

No studies reporting arrhythmia were available for the anticholinergic scopolamine (Summary of findings 10).

Visual disturbances within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of visual disturbances

Pairwise meta-analyses of visual disturbances comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for dexamethasone (Analysis 3.10), droperidol (Analysis 6.8), methylprednisolone (Analysis 9.4), metoclopramide (Analysis 10.9), ondansetron (Analysis 11.9), scopolamine (Analysis 17.6), and tropisetron (Analysis 18.10). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

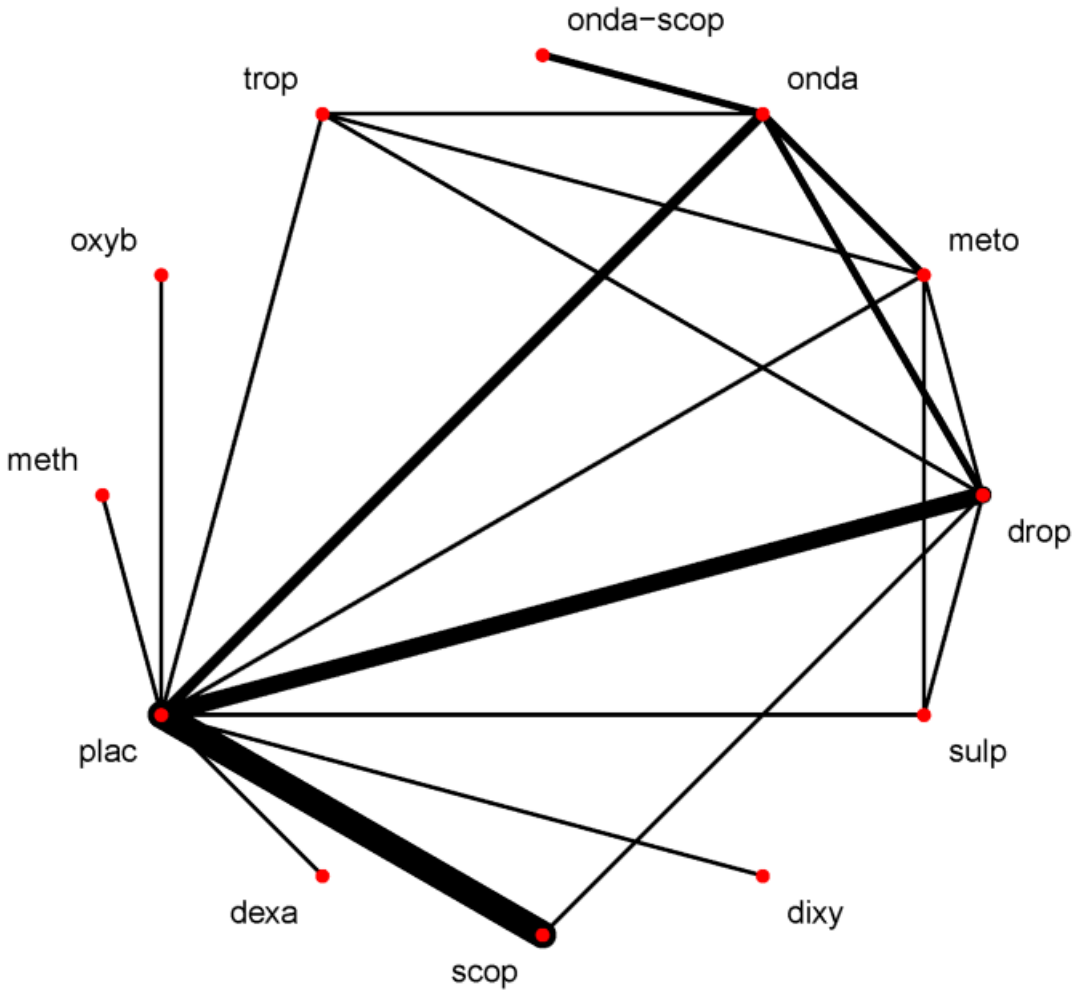
Primary analysis of visual disturbances: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome visual disturbances are available in an online repository (Supplementary Files-10-visual disturbances *; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).*

In total, 23 RCTs including 3815 participants were eligible for the network meta-analysis of visual disturbances. All studies have reported events in at least one study arm. Two studies were not connected to the network and were excluded from two analyses (Green 2012, comparison: aprepitant-scopolamine versus aprepitant; White 2007-1, comparison: dexamethasone-droperidol versus dexamethasone-scopolamine). The network of the remaining 21 studies included 12 different treatments (nodes) with 36 pair-wise comparisons due to multi-arm studies (Figure 26). The 12 treatments included one two-fold drug combination, 10 single drugs, and placebo or no treatment. The most common comparisons were scopolamine (k = 8), droperidol (k = 5), and ondansetron (k = 3), all compared to placebo. Of the single drugs of direct interest, dexamethasone and methylprednisolone were poorly connected to the network, with placebo as the only comparator.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Figure 26. Network geometry of eligible comparisons for postoperative visual disturbances. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.

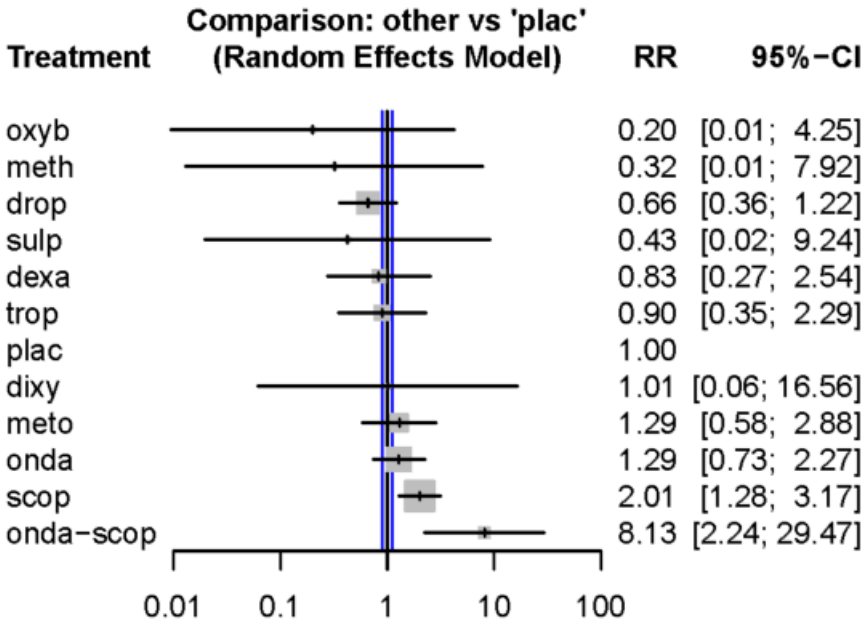


For 12 different treatments, 66 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 15 of 66 comparisons, direct and indirect evidence was available, whereas for five comparisons, only direct evidence was available, and for 46 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (risk ratio, RR) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 27. Of the 10 single drugs, scopolamine with RR 2.01 (95% CI 1.28 to 3.17) showed important harm (95% CI lower boundary > 1.11) compared to placebo for visual disturbances. Two single treatments showed harm (ondansetron, metoclopramide), one showed no or minimal effect (dixyrazine), six showed benefit (oxybutynin, methylprednisolone, droperidol, amisulpride, dexamethasone, tropisetron), and all treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects for all single drugs ranged between RR 0.20 (95% CI 0.01 to 4.25) for oxybutynin and RR 1.29 (95% CI 0.73 to 2.27) for ondansetron. Ondansetron-scopolamine, the only combination treatment, showed important harm compared to placebo, with RR 8.13 (95% CI 2.24 to 29.47).

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Figure 27. Forest plot of network meta-analysis of all trials for postoperative visual disturbances. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to 1.11). Treatments are ranked according to safety based on P scores. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



The estimated value of between-study variance for the network meta-analysis of visual disturbances was 0.0567 (tau^2) (I^2 = 11.9%). For the random-effects model, there was no heterogeneity within designs (Q = 11.23, df = 9, P = 0.26) and no inconsistency between designs (Q = 8.06, df = 8, P = 0.43). Clinically relevant heterogeneity for comparisons of direct interest (single drugs of direct interest compared to placebo) was detected only for scopolamine because the 95% PI included a different clinical implication compared to the 95% CI. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed no disagreement (direct versus indirect) for any of the 15 comparisons. There was no clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo.

Sensitivity analyses of visual disturbances

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of visual disturbances: risk of bias

Seven (33%) of 21 studies were rated as having high risk of overall bias, nine (43%) as unclear, and five (24%) as low. The network geometry of the five studies with low risk of bias included seven treatments. Six treatments were single drugs, and one was placebo. Of the single drugs of direct interest included in the primary network meta-analysis for visual disturbances, methylprednisolone, scopolamine, and tropisetron were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Comparison of treatment effects of

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

the sensitivity analysis for risk of bias and the primary network meta-analysis for visual disturbances with placebo as reference compound revealed a non-robust treatment effect for droperidol. Droperidol compared to placebo with RR 1.06 (95% CI 0.12 to 9.25) showed no or minimal effect associated with uncertainty. No between-study variance for this sensitivity network meta-analysis of visual disturbances was estimable because each comparison was represented by only one study.

Reporting bias (visual disturbances)

None of the direct pair-wise comparisons included 10 or more studies. Therefore, analyses investigating reporting or publication bias were not performed.

Subgroup analysis of visual disturbances: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis for visual disturbances including single drugs only (and excluding combination treatments) with 19 studies and 11 treatments including placebo was conducted. Network geometry, effect estimates, and the ranking order of drugs were robust compared to the primary analysis, including combination prophylaxis. The estimated value of between-study variance for the network meta-analysis of single drugs for visual disturbances was 0.0787 (tau^2) (I^2 = 16.3%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. Droperidol and ondansetron were split into high and recommended dose categories. For dexamethasone, methylprednisolone, metoclopramide, and tropisetron, only one dose category was available for subgroup analysis. Drugs without any dose recommendation according to Table 1 (scopolamine) and drugs not of direct interest (dixyrazine, oxybutynin, sulpiride) were lumped together, irrespective of the doses being analysed, in the category 'NA'. Jokela 2002 was excluded from the subgroup analysis because the interventions were not associated with one of the three dose categories (metoclopramide 'NA', tropisetron 'NA'). The network consisted of 18 studies, with 11 treatments including placebo split into 13 nodes with dose categories. In the ranking of treatments according to safety with placebo as the reference compound, recommended doses of ondansetron ranked higher than high doses. High doses of droperidol ranked higher than recommended doses. Overall, the 95% CIs between different doses of all single drugs overlapped, and the uncertainty of treatment effects was considerable, limiting reliable conclusions. The estimated value of between-study variance for this subgroup network meta-analysis of single drugs for visual disturbances was 0.1842 (tau^2) (I^2 = 28.6%).

Sensitivity analysis of visual disturbances: comparability of doses

In four (21%) of 19 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis consisted of five treatments including placebo. Of the single drugs of direct interest included in the primary network meta-analysis for visual disturbances, metoclopramide, scopolamine, and tropisetron were not included in the sensitivity analysis due to lack of studies with comparable doses. Estimated treatment effects for all other single drugs of direct interest were robust in the sensitivity analysis with placebo as the reference compound. The estimated value of between-study variance for this sensitivity network meta-analysis of visual disturbances was 0 (tau^2) (I^2 = 0%).

Certainty of evidence: visual disturbances

The certainty of evidence of treatment estimates for visual disturbances evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 11).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for visual disturbances ranged from very low to low (Summary of findings 11). Ondansetron (RR 1.29, 95% CI 0.73 to 2.27) compared to placebo may increase visual disturbances, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether tropisetron (RR 0.90, 95% CI 0.35 to 2.29) compared to placebo reduces visual disturbances, with very low-certainty evidence (very serious concerns for study limitations and imprecision). No studies reporting visual disturbances were available for dolasetron, granisetron, palonosetron, and ramosetron.

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for visual disturbances ranged from very low to low (Summary of findings 11). Metoclopramide (RR 1.29, 95% CI 0.58 to 2.88) compared to placebo may increase visual disturbances, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether droperidol (RR 0.66, 95% CI 0.36 to 1.22) compared to placebo reduces visual disturbances, with very low-certainty evidence (study limitations, very serious concerns for imprecision). No studies reporting visual disturbances were available for amisulpride, haloperidol, and perphenazine.

No studies reporting visual disturbances were available for relevant NK_1 receptor antagonists (Summary of findings 11).

For relevant corticosteroids (compared to placebo), the certainty of evidence of network effect estimates for visual disturbances was assessed as low and very low (Summary of findings 11). Dexamethasone (RR 0.83, 95% CI 0.27 to 2.54) may reduce visual disturbances compared to placebo, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether methylprednisolone (RR 0.32, 95% CI 0.01 to 7.92) compared to placebo reduces visual disturbances, with very low-certainty evidence (very serious concerns for study limitations and imprecision). For both comparisons, only direct evidence was available.

No studies reporting visual disturbances were available for relevant antihistamines (Summary of findings 11).

The anticholinergic scopolamine (RR 2.01, 95% CI 1.28 to 3.17) may increase visual disturbances compared to placebo, with low-certainty evidence (Summary of findings 11). The certainty of evidence was limited due to study limitations and heterogeneity.

QT prolongation within seven days postoperatively

Pairwise meta-analyses (single drugs of direct interest versus placebo) of QT prolongation

Pairwise meta-analyses for QT prolongation comparing single drugs of direct interest versus placebo are presented in the Data and analyses section and were available for dexamethasone (Analysis 3.11), droperidol (Analysis 6.9), haloperidol (Analysis 8.5), ondansetron (Analysis 11.10), palonosetron (Analysis 12.8), and tropisetron (Analysis 18.11). Studies or study arms were separated according to dose categories of single drugs (low, recommended, high, NA).

Primary analysis of QT prolongation: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome QT prolongation are available in an online repository (Supplementary Files-11-QT prolongation *; including direct and indirect effect estimates to the primary NMA, network graphs, and forest plots to all sensitivity and subgroup analyses, explorative analyses of reporting bias, and funnel plots).*

In total, 18 RCTs with 37 pair-wise comparisons due to multi-arm studies including 4440 participants were eligible for the network meta-analysis of QT prolongation. Eight studies (44%) have reported zero events in all study arms. The network consisted of 13 different treatments (nodes), including four two-fold drug combinations, eight single drugs, and placebo or no treatment (Figure 28). The most common comparisons were haloperidol (k = 4) and droperidol (k = 3) compared to placebo, aprepitant (k = 3), and haloperidol (k = 3) compared to ondansetron, and dexamethasone-haloperidol compared to dexamethasone (k = 3). Of the single drugs of direct interest, aprepitant and tropisetron were poorly connected to the network, with ondansetron and placebo, respectively, as the only comparators.

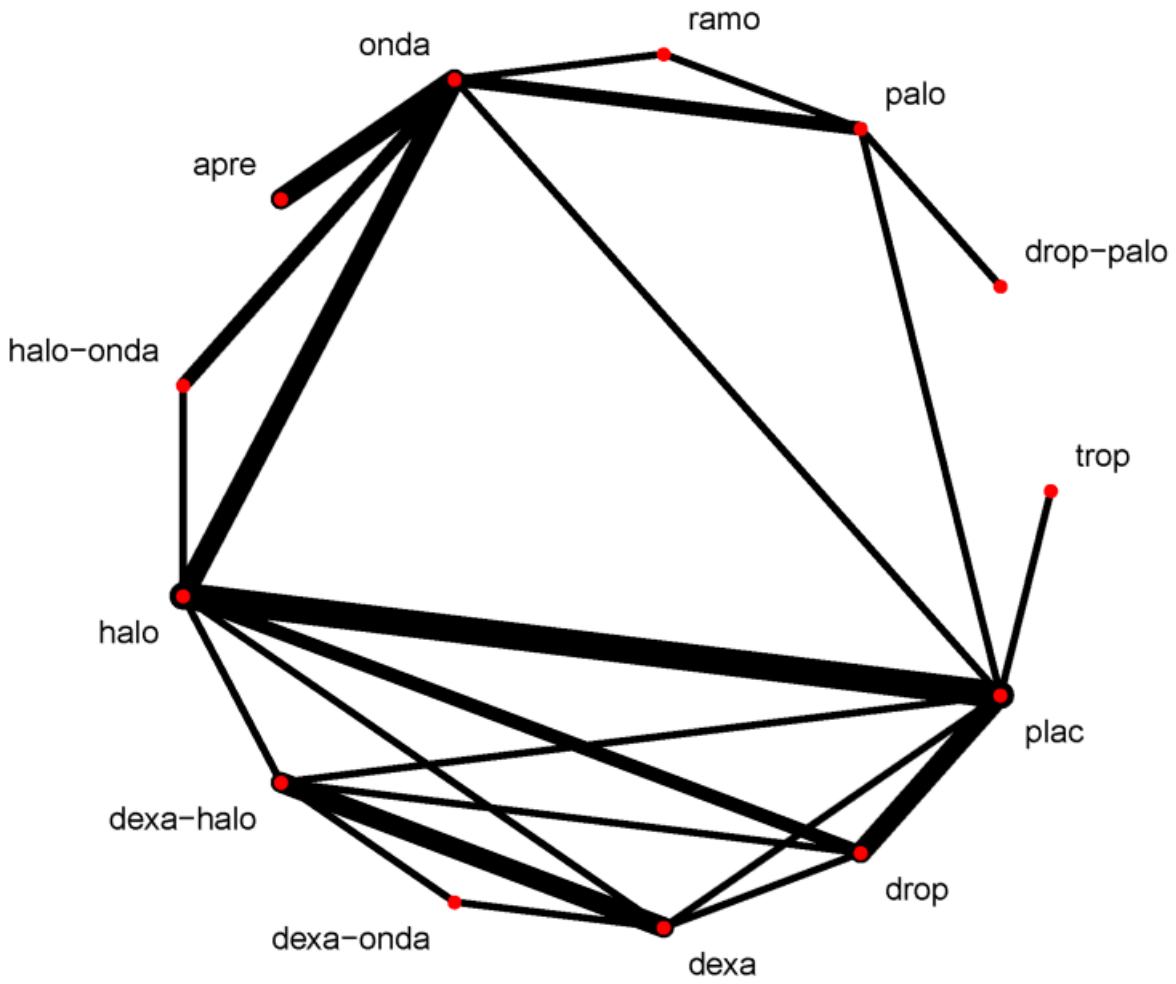
Figure 28. Network geometry of eligible comparisons for postoperative QT prolongation. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



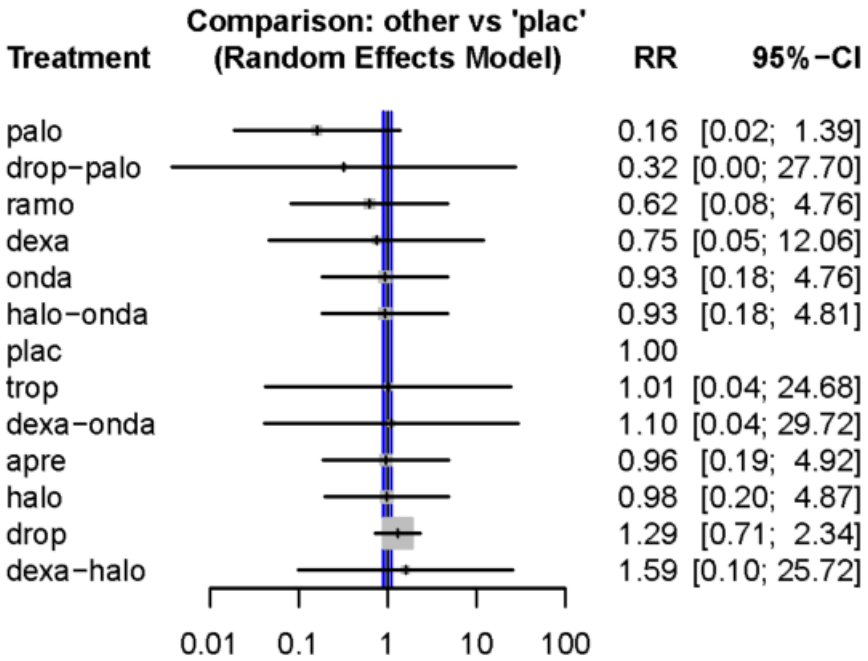
For 13 different treatments, 78 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 19 of 78 comparisons, direct and indirect evidence was available, whereas for four comparisons, only direct evidence was available, and for 55 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (risk ratio, RR) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 29. In terms of QT prolongation, none of the eight single drugs showed important benefit (95% CI upper boundary < 0.9) or important harm (95% CI lower boundary > 1.11) compared to placebo. Three single treatments showed benefit (palonosetron, ramosetron, dexamethasone), four showed no or minimal effect (ondansetron, tropisetron, aprepitant, haloperidol), one showed harm (droperidol), and all treatment effects were associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs ranged between RR 0.16 (95% CI 0.02 to 1.39) for palonosetron and RR 1.29 (95% CI 0.71 to 2.34) for droperidol. None of the combination treatments showed important benefit or important harm compared to placebo. One combination treatment showed benefit, two showed no or minimal effect, one showed harm, and all treatment effects were associated with

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

uncertainty. Treatment effects of combination treatments ranged between RR 0.32 (95% CI 0.00 to 27.70) for droperidol-palonosetron and RR 1.59 (95% CI 0.10 to 25.72) for dexamethasone-haloperidol.

Figure 29. Forest plot of network meta-analysis of all trials for postoperative QT prolongation. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.9 to 1.11). Treatments are ranked according to safety based on P scores. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



The estimated value of between-study variance for the network meta-analysis of QT prolongation was 0 (tau^2) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 3.32, df = 2, P = 0.19) and no inconsistency between designs (Q = 1.78, df = 12, P = 1.00). No clinically relevant heterogeneity for comparisons of direct interest (single drugs of direct interest compared to placebo) was noted because 95% CIs and 95% PIs were compatible with respect to the range of equivalence. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed no disagreement (direct versus indirect) for any of the 19 comparisons. There was no clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo.

Sensitivity analyses of QT prolongation

Sensitivity analyses included all single drugs and drug combinations, but results are described only for single drugs of direct interest compared to placebo.

Sensitivity analysis of QT prolongation: risk of bias

For QT prolongation, five (28%) of 18 studies were rated as having high risk of overall bias, six (33%) as unclear, and seven (39%) as low. One study with low risk of bias was not connected to the network for low risk of bias studies and was excluded from the sensitivity analysis (Hu 2017, comparison: droperidol-palonosetron versus palonosetron). The network geometry of the six remaining studies with low risk of bias included five treatments, of which

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

four were single drugs and one was placebo. Of the single drugs of direct interest included in the primary network meta-analysis for QT prolongation, dexamethasone, palonosetron, ramosetron, and tropisetron were not included in the sensitivity network meta-analysis due to lack of studies with low risk of bias. Comparison of treatment effects of the sensitivity analysis for risk of bias and the primary network meta-analysis for QT prolongation with placebo as the reference compound revealed robust treatment effects for all included single drugs of direct interest. The estimated value of between-study variance for the sensitivity network meta-analysis of QT prolongation was 0 (tau^2) (I^2 = 0%).

Reporting bias (QT prolongation)

None of the direct pair-wise comparisons included 10 or more studies. Therefore, analyses investigating reporting or publication bias were not performed.

Subgroup analysis of QT prolongation: dose effects

The treatment effect modifier dose was investigated in a subgroup network meta-analysis splitting drugs into the categories low, recommended, and high doses according to Table 1. Splitting of doses was restricted to single drugs.

First, a network meta-analysis for QT prolongation including single drugs only (and excluding combination treatments) with 14 studies and nine treatments including placebo was conducted. Network geometry, effect estimates, and the ranking order of drugs were similar compared to the primary analysis, including combination prophylaxis. However, the comparison dexamethasone versus placebo (RR 1.09, 95% CI 0.04 to 27.88) showed a slightly changed treatment effect, changing clinical interpretation from benefit to no or minimal effect, both associated with uncertainty. The estimated value of between-study variance for the network meta-analysis of single drugs for QT prolongation was 0 (tau^2) (I^2 = 0%).

Second, the subgroup analysis of dose was conducted for the network of single drugs only. The following drugs were split into dose categories: aprepitant, haloperidol, palonosetron, and tropisetron. For dexamethasone, droperidol, ondansetron, and ramosetron, only one dose category was available for subgroup analysis. The network consisted of 14 studies with eight treatments including placebo split into 14 nodes with dose categories. In the ranking of treatments according to safety with placebo as the reference compound, high and recommended doses of tropisetron ranked higher than low doses. Low and recommended doses of palonosetron showed benefit associated with uncertainty, and recommended and high doses of haloperidol showed harm associated with uncertainty. Recommended and high doses of aprepitant showed harm, which is in contrast to the primary network meta-analysis of QT prolongation. Overall, the 95% CIs between different doses of all single drugs overlapped, and the uncertainty of treatment effects was considerable, limiting reliable conclusions. The estimated value of between-study variance for this subgroup network meta-analysis of single drugs for QT prolongation was 0 (tau^2) (I^2 = 0%).

Sensitivity analysis of QT prolongation: comparability of doses

In eight (57%) of 14 studies investigating single drugs, comparable doses of antiemetic drugs were analysed (comparable dose categories). The analysis included only studies investigating drugs of direct interest for which dose recommendations were described and that were assigned to one of the dose categories according to Table 1. The network of this sensitivity analysis consisted of seven treatments including placebo. Of the single drugs of direct interest included in the primary network meta-analysis for QT prolongation, aprepitant and dexamethasone were not included in the sensitivity analysis due to lack of studies with comparable doses. Estimated treatment effects for the other single drugs of direct interest were robust in the sensitivity analysis with placebo as the reference compound, except for ondansetron. Ondansetron (RR 0.75, 95% CI 0.05 to 10.48) showed benefit associated with uncertainty compared to placebo. The estimated value of between-study variance for this sensitivity network meta-analysis of QT prolongation was 0 (tau^2) (I^2 = 0%).

Certainty of evidence: QT prolongation

The certainty of evidence of treatment estimates for QT prolongation evaluated with CINeMA is summarized in the 'Summary of findings' table for drugs of direct interest compared to placebo (Summary of findings 12).

For relevant 5-HT_3 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for QT prolongation ranged from very low to low (Summary of findings 12). Ondansetron (RR 0.93, 95% CI 0.18 to 4.76) compared to placebo may have little or no effect on QT prolongation, with low-certainty evidence (very serious concerns for imprecision). We are uncertain whether palonosetron (RR 0.16, 95% CI 0.02 to 1.39) reduces QT prolongation compared to placebo, with very low-certainty evidence (study limitations, very serious concerns for imprecision). We are uncertain whether tropisetron (RR 1.01, 95% CI 0.04 to 24.68) compared to placebo has little or no effect on QT prolongation, with very low-certainty evidence (very serious concerns for study limitations and imprecision) and direct evidence only. We are uncertain whether ramosetron (RR 0.62, 95% CI 0.08 to 4.76) reduces QT prolongation, with only indirect evidence and very low-certainty evidence (study limitations, incoherence, very serious concerns for imprecision). No studies reporting QT prolongation were available for dolasetron and granisetron.

For relevant D_2 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for QT prolongation was assessed as low (Summary of findings 12). Droperidol (RR 1.29, 95% CI 0.71 to 2.34) may increase QT prolongation, and haloperidol (RR 0.98, 95% CI 0.20 to 4.87) may have little or no effect on QT prolongation, compared to placebo, both with low-certainty evidence (very serious concerns for imprecision). No studies reporting QT prolongation were available for amisulpride, metoclopramide, and perphenazine.

For the relevant NK_1 receptor antagonists (compared to placebo), the certainty of evidence of network effect estimates for QT prolongation was assessed as very low (Summary of findings 12). We are uncertain whether aprepitant (RR 0.96, 95% CI 0.19 to 4.92) may have little or no effect on QT prolongation, with very low-certainty evidence (incoherence, very serious concerns for imprecision) and indirect evidence only. No studies reporting QT prolongation were available for casopitant, fosaprepitant, and rolapitant.

For relevant corticosteroids (compared to placebo), the certainty of evidence of network effect estimates for QT prolongation was assessed as very low (Summary of findings 12). We are uncertain whether dexamethasone (RR 0.75, 95% CI 0.05 to 12.06)

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

reduces QT prolongation compared to placebo, with very low-certainty evidence (study limitations, very serious concerns for imprecision). No studies reporting QT prolongation were available for methylprednisolone.

No studies reporting QT prolongation were available for relevant antihistamines (Summary of findings 12).

No studies reporting QT prolongation were available for the anticholinergic scopolamine (Summary of findings 12).

Secondary outcomes (not GRADE-relevant)

Assessment of the certainty of evidence was not performed for the following secondary outcomes.

Mortality within seven days postoperatively

Primary analysis of mortality: network meta-analyses with all single drugs and drug combinations

In total, 17 RCTs including 6840 participants have reported mortality in the published study report. Only one participant with ondansetron died due to pulmonary embolism during the observation period in the study of Morris 1998 comparing metoclopramide, ondansetron, and placebo. Study authors reported that the participant's death was not drug-related. All other studies have reported zero events in all study arms. Due to the low event rate, we did not perform a network meta-analysis. In total, data on mortality were reported for five drug combinations (casopitant-ondansetron, dexamethasone-granisetron, dexamethasone-ondansetron, dexamethasone-palonosetron, ondansetron-vestipitant) and seven single drugs (amisulpride, casopitant, dexamethasone, dolasetron, metoclopramide, ondansetron, palonosetron).

Early vomiting within 0 to 2 to 6 hours postoperatively or in PACU

Primary analysis of early vomiting: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome early vomiting are available in an online repository (Supplementary Files-12-early vomiting *; including direct and indirect effect estimates to the primary NMA, explorative analyses of reporting bias, and funnel plots).*

In total, 264 RCTs including 37,928 participants were eligible for the network meta-analysis of early vomiting. Twenty-one studies (8%) have reported zero events in all study arms. One study was not connected to the network and was excluded from the following analysis: Rennemo 1982, comparison: droperidol-scopolamine versus levomepromazine-scopolamine. The network of the remaining 263 studies included 69 different treatments (nodes), with 564 pair-wise comparisons due to multi-arm studies (Figure 30). The 69 treatments included 34 drug combinations (28 times: two-fold, five times: three-fold, once: four-fold), 34 single drugs, and placebo or no treatment. The most common comparisons were ondansetron (k = 60 studies), dexamethasone (k = 39), droperidol (k = 28), metoclopramide (k = 21), and granisetron (k = 13), all compared to placebo, and dexamethasone-ondansetron (k = 19), as well as dexamethasone (k = 16), compared to ondansetron. Of the single drugs of direct interest, aprepitant and fosaprepitant were poorly connected to the network, with placebo and ondansetron as the only comparators, respectively.

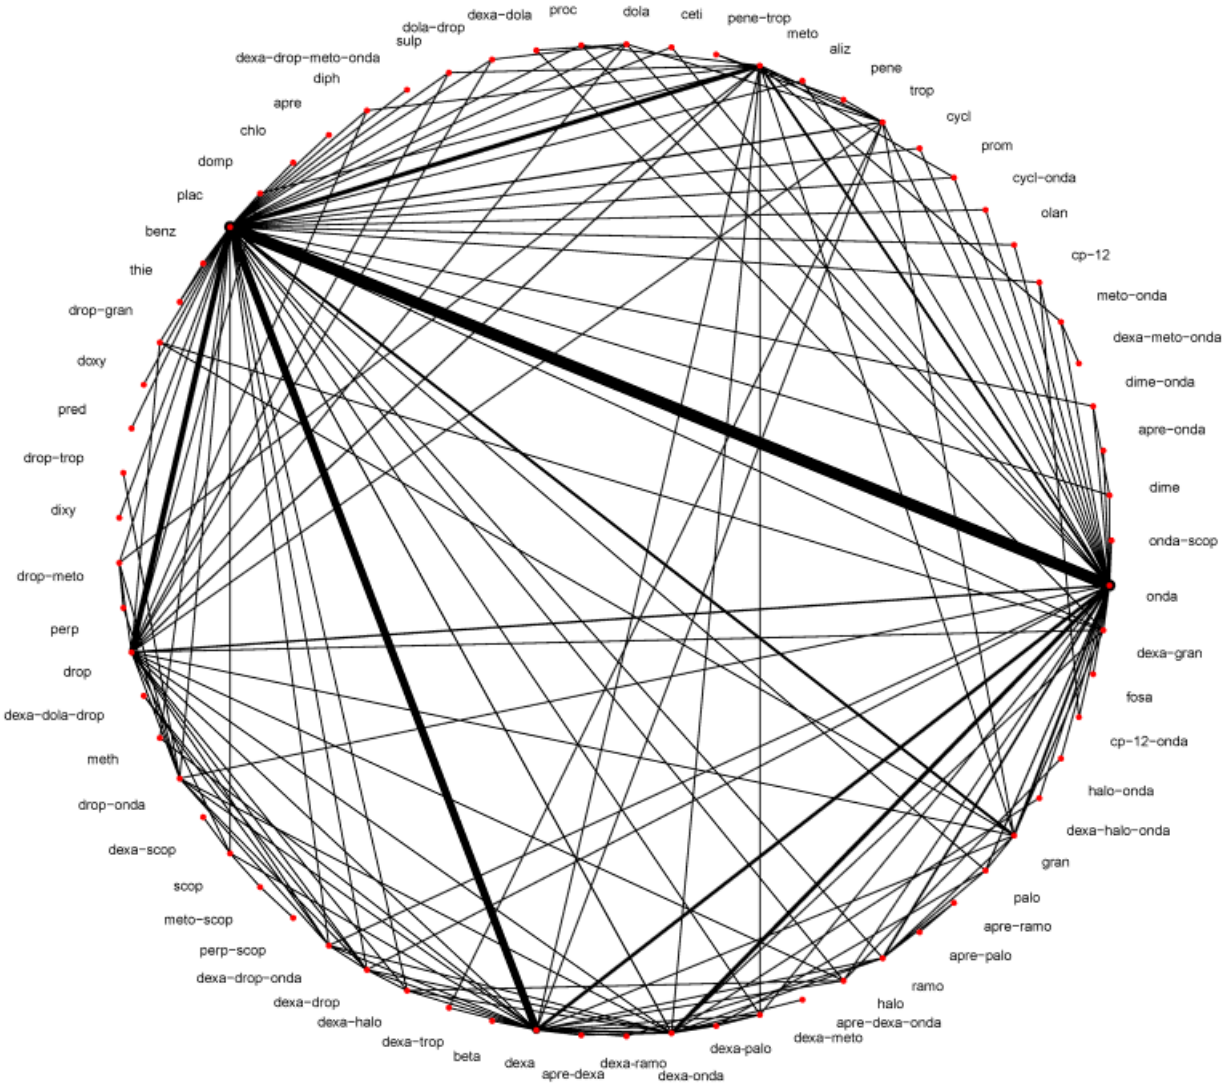
Figure 30. Network geometry of eligible comparisons for early postoperative vomiting. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



For 69 different treatments, 2346 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 149 of 1378 comparisons, direct and indirect evidence was available, whereas for 24 comparisons, only direct evidence was available, and for 2173 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (RR with 95% CI) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 31. In terms of preventing early vomiting, 14 of all 34 single drugs showed important benefit (95% CI upper boundary < 0.8) compared to placebo, with RRs ranging between 0.10 (95% CI 0.03 to 0.34) for fosaprepitant and 0.50 (95% CI 0.43 to 0.59) for dexamethasone. Amongst the most effective single drugs of direct interest with important benefit for early vomiting prophylaxis compared to placebo in decreasing order according to P scores were fosaprepitant, promethazine, haloperidol, granisetron, dolasetron, ramosetron, droperidol, ondansetron, tropisetron, palonosetron, and dexamethasone. Fosaprepitant, the most effective drug in the network meta-analysis, was poorly connected to the network, with only three studies comparing fosaprepitant to ondansetron. Fifteen single drugs—four of direct interest (perphenazine, aprepitant, methylprednisolone,

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

dimenhydrinate)—showed benefit associated with uncertainty (95% CI crossing the range of equivalence). Five single drugs—two of direct interest (metoclopramide, scopolamine)—showed little or no effect associated with uncertainty. Treatment effects of all single drugs compared to placebo ranged between RR 0.10 (95% CI 0.03 to 0.34) for fosaprepitant and RR 0.89 (95% CI 0.55 to 1.44) for alizapride. Of all drug combinations, 23 out of 34 combinations showed important benefit compared to placebo, with RRs ranging between 0.01 (95% CI 0.00 to 0.31) for aprepitant-palonosetron and 0.38 (95% CI 0.23 to 0.64) for dexamethasone-metoclopramide. Ten drug combinations showed benefit associated with uncertainty (95% CI crossing the range of equivalence) compared to placebo, and one combination (perphenazine-scopolamine) showed harm associated with uncertainty. Treatment effects of drug combinations compared to placebo ranged between RR 0.01 (95% CI 0.00 to 0.31) for aprepitant-palonosetron and RR 1.50 (95% CI 0.41 to 5.46) for perphenazine-scopolamine.

Figure 31. Forest plot of network meta-analysis of all trials for early postoperative vomiting. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.8 to

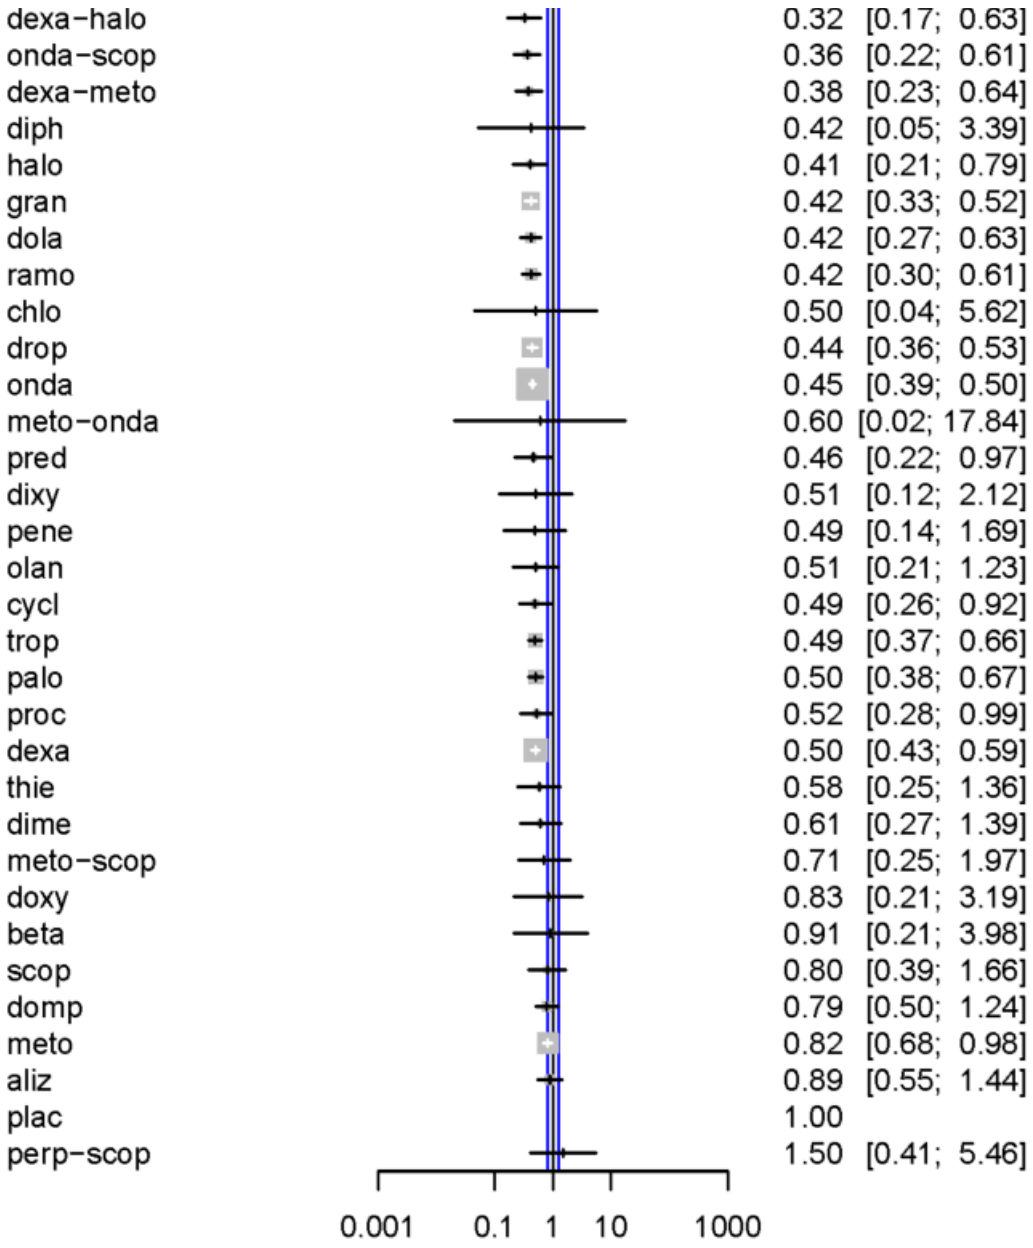
Figure 31. (Continued)



The estimated value of between-study variance for the network meta-analysis of early vomiting was 0.0574 (tau^2) (I^2 = 17.4%). For the random-effects model, there was no heterogeneity within designs (Q = 150.33, df = 153, P = 0.55) but inconsistency between designs (Q = 232.32, df = 163, P = 0.0003). When the full random-effects design-by-treatment interaction model was used, there was evidence of residual statistical inconsistency (Q = 232.32, df = 163, P = 0.0003). Clinically relevant heterogeneity for comparisons of direct interest (single drugs of direct interest compared to placebo) was detected for dexamethasone, haloperidol, metoclopramide, palonosetron, and tropisetron. In these cases, 95% PIs of treatment estimates included different clinical implications compared to the 95% CIs. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed disagreement (direct versus indirect) for nine out of 149 comparisons (dexamethasone versus ondansetron (P = 0.004), dexamethasone versus placebo (P = 0.02), dexamethasone-droperidol versus placebo (P = 0.04), dexamethasone-ondansetron versus dexamethasone-palonosetron (P = 0.02), dexamethasone-ondansetron versus ramosetron (P = 0.01), domperidone versus metoclopramide (P = 0.03), granisetron versus palonosetron (P = 0.01), palonosetron versus placebo (P = 0.005), palonosetron versus ramosetron (P = 0.045)). Clinically relevant incoherence of direct and indirect treatment estimates for single drugs of

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

direct interest compared to placebo was found for dolasetron, haloperidol, metoclopramide, palonosetron, and tropisetron.

Reporting bias (early vomiting)

Eleven direct pair-wise comparisons included 10 or more studies for which small-study effects such as reporting or publication bias were investigated: dexamethasone, droperidol, granisetron, metoclopramide, and ondansetron, all compared to placebo; dexamethasone, dexamethasone-ondansetron, granisetron, metoclopramide, and ramosetron, all compared to ondansetron; and dexamethasone-ondansetron compared to dexamethasone. Results of the funnel plots, the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. According to the explorative analyses, we did not suspect publication bias for any of the above mentioned comparisons. Small P values when the arcsine test was used to detect funnel plot asymmetry were found for ondansetron versus placebo (P = 0.09), dexamethasone versus placebo (P =0.003), dexamethasone versus ondansetron (P = 0.04), and droperidol versus placebo (P = 0.06). The contour-enhanced funnel plots suggested asymmetry for granisetron versus placebo and ondansetron versus placebo. However, we did not suspect relevant publication bias for these comparisons because trim and fill sensitivity analysis did not change the conclusion with respect to the range of equivalence.

Late vomiting (or dry retching) within 2 to 24 hours postoperatively

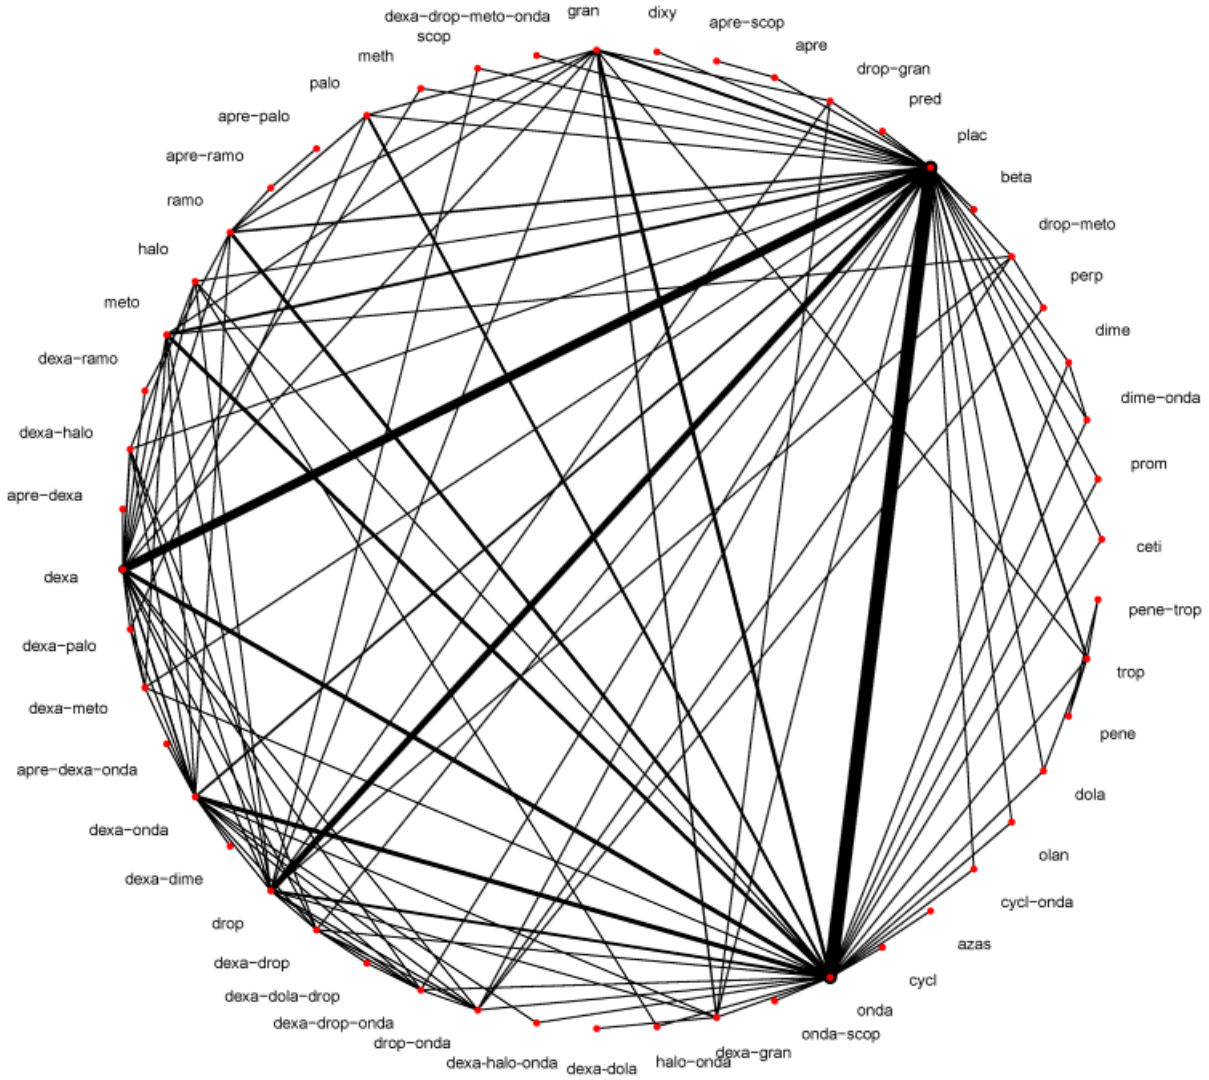
Primary analysis of late vomiting: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome late vomiting are available in an online repository (Supplementary Files-13-late vomiting *; including direct and indirect effect estimates to the primary NMA, explorative analyses of reporting bias, and funnel plots).*

In total, 206 RCTs including 28,547 participants were eligible for the network meta-analysis of late vomiting. Ten studies (5%) have reported zero events in all study arms. The network of the 206 studies included 51 different treatments (nodes), with 438 pair-wise comparisons due to multi-arm studies (Figure 32). The 51 treatments included 26 drug combinations (21 times: two-fold, four times: three-fold, once: four-fold), 24 single drugs, and placebo or no treatment. The most common comparisons were ondansetron (k = 46 studies), dexamethasone (k = 30), and droperidol (k = 21), all compared to placebo, and dexamethasone-ondansetron (k = 15), as well as dexamethasone (k = 14), compared to ondansetron. Of the single drugs of direct interest, aprepitant was poorly connected to the network, with placebo as the only comparator.

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Figure 32. Network geometry of eligible comparisons for late postoperative vomiting. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



For 51 different treatments, 1275 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 112 of 1275 comparisons, direct and indirect evidence was available, whereas for 18 comparisons, only direct evidence was available, and for 1145 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (RR with 95% CI) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 33. Of the 24 single drugs, eight drugs showed important benefit (95% CI upper boundary < 0.8) compared to placebo, with RRs ranging between 0.06 (95% CI 0.01 to 0.48) for azasetron and 0.57 (95% CI 0.51 to 0.63) for ondansetron. Amongst the most effective single drugs of direct interest with important benefit for late vomiting prophylaxis compared to placebo in decreasing order according to P scores were aprepitant, granisetron, ramosetron, palonosetron, tropisetron, dexamethasone, and ondansetron. Eleven single drugs, eight of direct interest (promethazine, methylprednisolone, perphenazine, dimenhydrinate, dolasetron, haloperidol, scopolamine, droperidol), showed benefit associated with uncertainty (95% CI crossing the range of equivalence). Three single drugs, one of direct interest (metoclopramide), showed little or no effect associated with uncertainty. Penehyclidine and

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

prednisolone, both not of direct interest, showed harm associated with uncertainty. Treatment effects of all single drugs compared to placebo ranged between RR 0.06 (95% CI 0.01 to 0.48) for azasetron and RR 1.44 (95% CI 0.68 to 3.03) for prednisolone. Of all 26 drug combinations, 18 combinations showed important benefit compared to placebo, with RRs ranging between 0.01 (95% CI 0.00 to 0.22) for aprepitant-palonosetron and 0.47 (95% CI 0.36 to 0.61) for ondansetron-scopolamine. Eight drug combinations showed benefit associated with uncertainty compared to placebo. Treatment effects of drug combinations compared to placebo ranged between RR 0.01 (95% CI 0.00 to 0.22) for aprepitant-palonosetron and RR 0.57 (95% CI 0.22 to 1.43) for droperidol-metoclopramide.

Figure 33. Forest plot of network meta-analysis of all trials for late postoperative vomiting. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.8 to

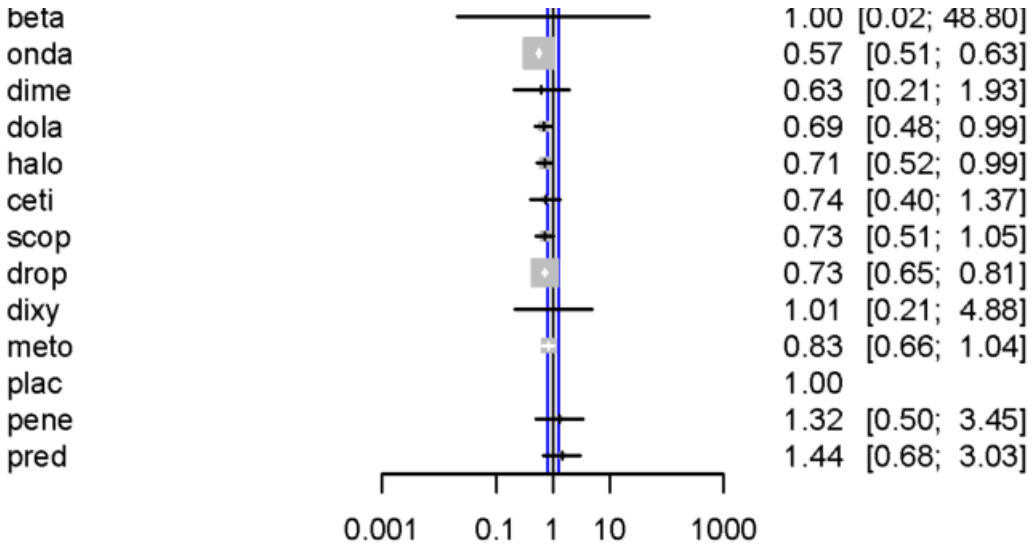
Figure 33. (Continued)



The estimated value of between-study variance for the network meta-analysis of late vomiting was 0 (tau²) (I^2 = 0%). For the random-effects model, there was no heterogeneity within designs (Q = 100.69, df = 114, P = 0.81) and no inconsistency between designs (Q = 145.54, df = 133, P = 0.22). No clinically relevant heterogeneity for comparisons of direct interest (single drugs of direct interest compared to placebo) was detectable because 95% CIs and 95% PIs were compatible with respect to the range of equivalence. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed disagreement (direct versus indirect) for 10 out of 112 comparisons (dexamethasone versus ondansetron (P = 0.03), dexamethasone-droperidol versus dexamethasone-droperidol-ondansetron (P = 0.02), dexamethasone-droperidol versus droperidol (P = 0.03), dexamethasone-droperidol-ondansetron versus dexamethasone-ondansetron (P = 0.002), dexamethasone-ondansetron versus droperidol (P = 0.003), dexamethasone-ondansetron versus droperidol-ondansetron (P = 0.03), dexamethasone-ondansetron versus placebo (P = 0.02), dolasetron versus ondansetron (P = 0.003), dolasetron versus placebo (P = 0.006), droperidol versus placebo (P = 0.001)). Clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo was found for dolasetron and metoclopramide.

Reporting bias (late vomiting)

Nine direct pair-wise comparisons included 10 or more studies for which small-study effects such as reporting or publication bias were investigated: dexamethasone, droperidol, granisetron, and ondansetron, all compared to placebo; and dexamethasone, dexamethasone-ondansetron, granisetron, metoclopramide, and ramosetron, all compared to ondansetron. Results of the funnel plots, the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. According to the explorative analyses, we did not suspect publication bias for any of the above mentioned comparisons. A small P value when the arcsine test was used to detect funnel plot asymmetry was found for ondansetron versus placebo (P = 0.002). The contour-enhanced funnel plots suggested asymmetry for dexamethasone versus placebo. However, we did not suspect relevant publication bias for these comparisons because trim and fill sensitivity analysis did not change the conclusion with respect to the range of equivalence.

Nausea (or PONV) within 24 hours postoperatively

Primary analysis of nausea: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome nausea are available in an online repository (Supplementary Files-14-nausea *; including direct and indirect effect estimates to the primary NMA, explorative analyses of reporting bias, and funnel plots).*

In total, 325 RCTs including 55,208 participants were eligible for the network meta-analysis of nausea. All studies have reported events in at least one study arm. One study was not connected to the network and was excluded from the following analysis: Bergese 2016, comparison: aprepitant-dexamethasone-promethazine versus dexamethasone-ondansetron-promethazine. The network of the remaining 324 studies included 65 different treatments (nodes), with 670 pair-wise comparisons due to multi-arm studies (Figure 34). The 65 treatments included 35 drug combinations (30 times: two-fold, four times: three-fold, once: four-fold), 29 single drugs, and placebo or no treatment. The most common comparisons were ondansetron (k = 87 studies), dexamethasone (k = 53), droperidol (k = 50), metoclopramide (k = 30), granisetron (k = 20), and tropisetron (k = 15), all compared to placebo, and metoclopramide (k = 17), dexamethasone-ondansetron (k = 16), droperidol (k = 16), and dexamethasone (k = 14), all compared to ondansetron. Three single drugs of direct interest were poorly connected to the network. Amisulpride was connected only to placebo; aprepitant and fosaprepitant were connected only to ondansetron.

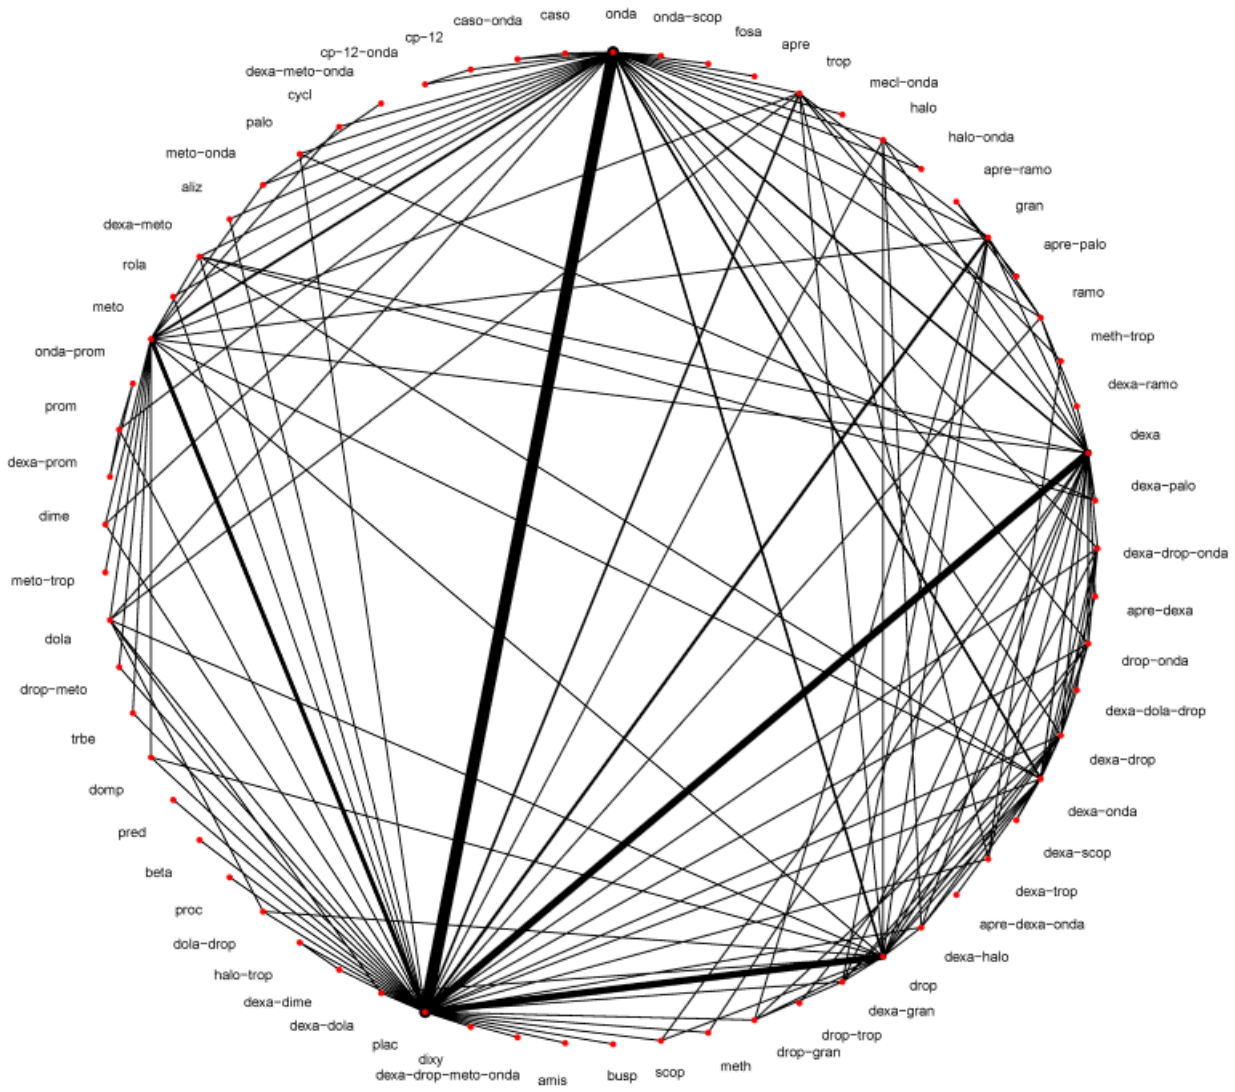
Figure 34. Network geometry of eligible comparisons for postoperative nausea within 24 hours postoperatively. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



For 65 different treatments, 2080 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 135 of 2080 comparisons, direct and indirect evidence was available, whereas for 24 comparisons, only direct evidence was available, and for 1921 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (RR with 95% CI) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 35. In terms of preventing nausea, of the 29 single drugs, nine showed important benefit (95% CI upper boundary < 0.8) compared to placebo, with RRs ranging between 0.31 (95% CI 0.13 to 0.74) for dixyrazine and 0.69 (95% CI 0.65 to 0.74) for ondansetron. Amongst the most effective single drugs of direct interest with important benefit for nausea prophylaxis compared to placebo in decreasing order according to P scores were methylprednisolone, ramosetron, droperidol, palonosetron, granisetron, dexamethasone, tropisetron, and ondansetron. Eleven single drugs, nine of direct interest

(dimenhydrinate, aprepitant, promethazine, scopolamine, haloperidol, fosaprepitant, casopitant, amisulpride, dolasetron), showed benefit associated with uncertainty (95% CI crossing the range of equivalence). Nine single drugs, two of direct interest (rolapitant, metoclopramide), showed little or no effect associated with uncertainty. Treatment effects of all single drugs compared to placebo ranged between RR 0.31 (95% CI 0.13 to 0.74) for dixyrazine and RR 1.14 (95% CI 0.74 to 1.74) for cyclizine. Of the 35 drug combinations, 27 combinations showed important benefit compared to placebo, with RRs ranging between 0.05 (95% CI 0.01 to 0.41) for dexamethasone-metoclopramide-ondansetron and 0.53 (95% CI 0.39 to 0.71) for dexamethasone-metoclopramide. Eight drug combinations showed benefit associated with uncertainty compared to placebo. Treatment effects of drug combinations compared to placebo ranged between RR 0.05 (95% CI 0.01 to 0.41) for dexamethasone-metoclopramide-ondansetron and RR 0.72 (95% CI 0.38 to 1.34) for droperidol-metoclopramide.

Figure 35. Forest plot of network meta-analysis of all trials for postoperative nausea within 24 hours postoperatively. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR < 1 favours the intervention, RR > 1 favours placebo. The blue lines indicate the range of equivalence (RR = 0.8 to 1.25). Treatments are ranked according to efficacy based on P scores.

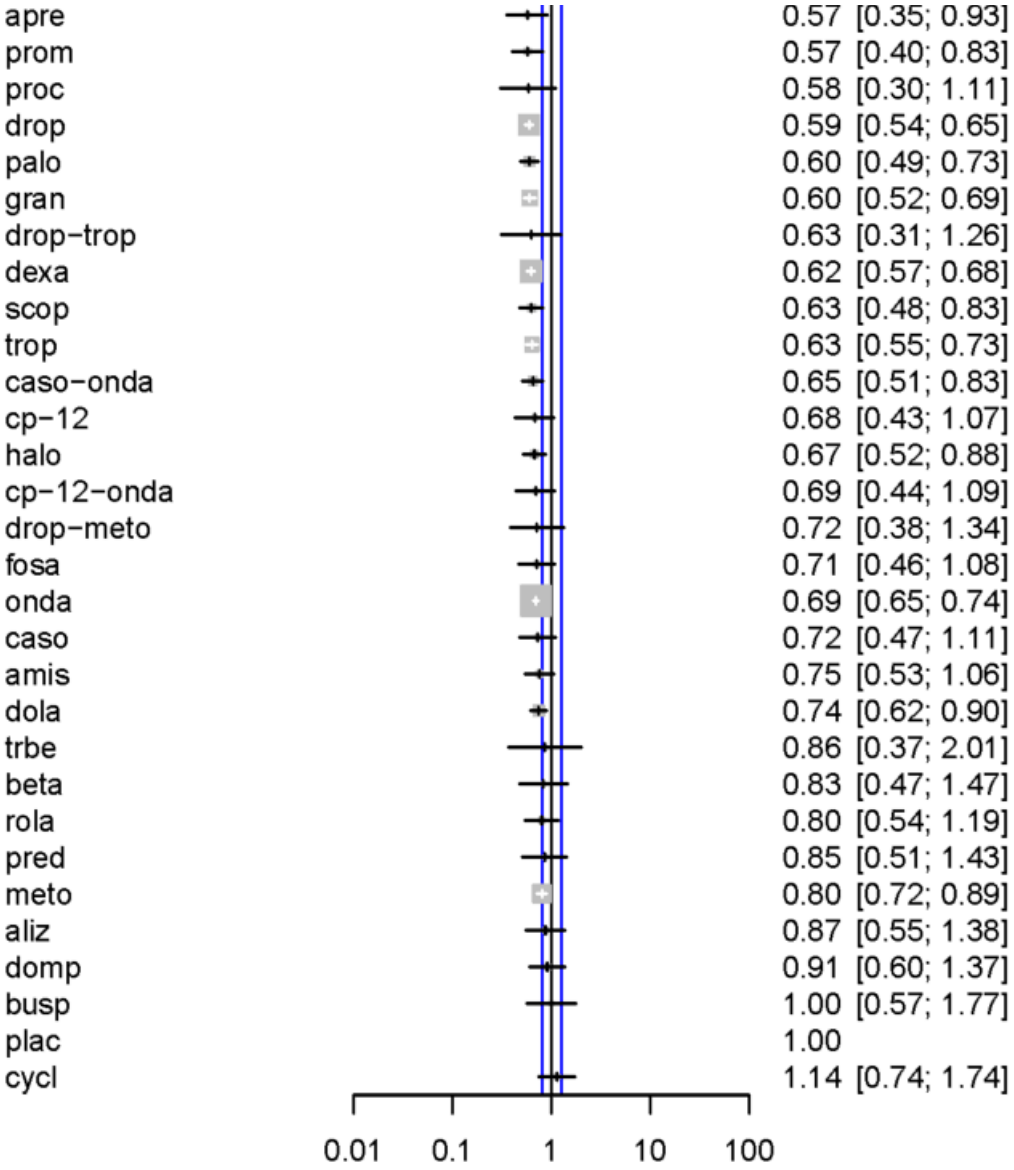
Figure 35. (Continued)



The estimated value of between-study variance for the network meta-analysis of nausea was 0.0524 (tau^2) (I^2 = 55.5%). For the random-effects model, there was heterogeneity within designs (Q = 546.86, df = 234, P < 0.0001) and inconsistency between designs (Q = 356.60, df = 168, P < 0.0001). When the full random-effects design-by-treatment interaction model was used, there was no evidence of residual statistical inconsistency (Q = 180.00, df = 168, P = 0.25). Clinically relevant heterogeneity for comparisons of direct interest (single drugs of direct interest compared to placebo) was detected for amisulpride, casopitant, dexamethasone, droperidol, fosaprepitant, granisetron, methylprednisolone, metoclopramide, ondansetron, palonosetron, ramosetron, rolapitant, and tropisetron. In these cases, 95% PIs of treatment estimates included different clinical implications compared to the 95% CIs. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed disagreement (direct versus indirect) for five out of 135 comparisons (dexamethasone versus dexamethasone-granisetron (P = 0.01), dexamethasone-granisetron versus dexamethasone-ondansetron (P = 0.02), dexamethasone-metoclopramide versus metoclopramide (P = 0.01), droperidol-granisetron versus granisetron (P = 0.02), ondansetron versus palonosetron (P = 0.02)). Clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo

was found for haloperidol, palonosetron, promethazine, and rolapitant.

Reporting bias (nausea)

Eleven direct pair-wise comparisons included 10 or more studies for which small-study effects such as reporting or publication bias were investigated: dexamethasone, droperidol, granisetron, metoclopramide, ondansetron, and tropisetron, all compared to placebo; dexamethasone, dexamethasone-ondansetron, droperidol, and metoclopramide, all compared to ondansetron; and dexamethasone-ondansetron compared to dexamethasone. Results of the funnel plots, the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. According to the explorative analyses, we suspected publication bias for the comparisons tropisetron versus placebo (P = 0.08), dexamethasone-ondansetron versus dexamethasone (P = 0.04), and dexamethasone-ondansetron versus ondansetron (P = 0.37). Small P values when the arcsine test was used to detect funnel plot asymmetry were also found for droperidol versus placebo (P = 0.047) and metoclopramide versus placebo (P = 0.07). The contour-enhanced funnel plots suggested asymmetry for dexamethasone, granisetron, and droperidol versus placebo. However, we did not suspect relevant publication bias for these comparisons because trim and fill sensitivity analysis did not change the conclusion with respect to the range of equivalence. Asymmetry may have been caused by other factors such as heterogeneity.

Complete response (no nausea or vomiting or need for rescue antiemetics) within 24 hours postoperatively

Primary analysis of complete response: network meta-analysis with all single drugs and drug combinations

Raw data of individual studies and all analyses for the outcome complete response are available in an online repository (Supplementary Files-15-complete response ; including direct and indirect effect estimates to the primary NMA, explorative analyses of reporting bias, and funnel plots).

In total, 137 RCTs including 30,254 participants were eligible for the network meta-analysis of complete response. All studies have reported events in at least one study arm. One three-arm study was not connected to the network and was excluded from the following analysis: Gandhi 2009, comparison: promethazine versus dexamethasone-promethazine versus ondansetron-promethazine). The network of the remaining 136 studies included 38 different treatments (nodes), with 278 pair-wise comparisons due to multi-arm studies (Figure 36). The 38 treatments included 20 drug combinations (19 times: two-fold, once: three-fold), 17 single drugs, and placebo or no treatment. The most common comparisons were ondansetron (k = 35 studies), droperidol (k = 19), and dexamethasone (k = 17), all compared to placebo. Four single drugs of direct interest were poorly connected to the network. Amisulpride and scopolamine were connected only to placebo, and aprepitant and fosaprepitant were connected only to ondansetron.

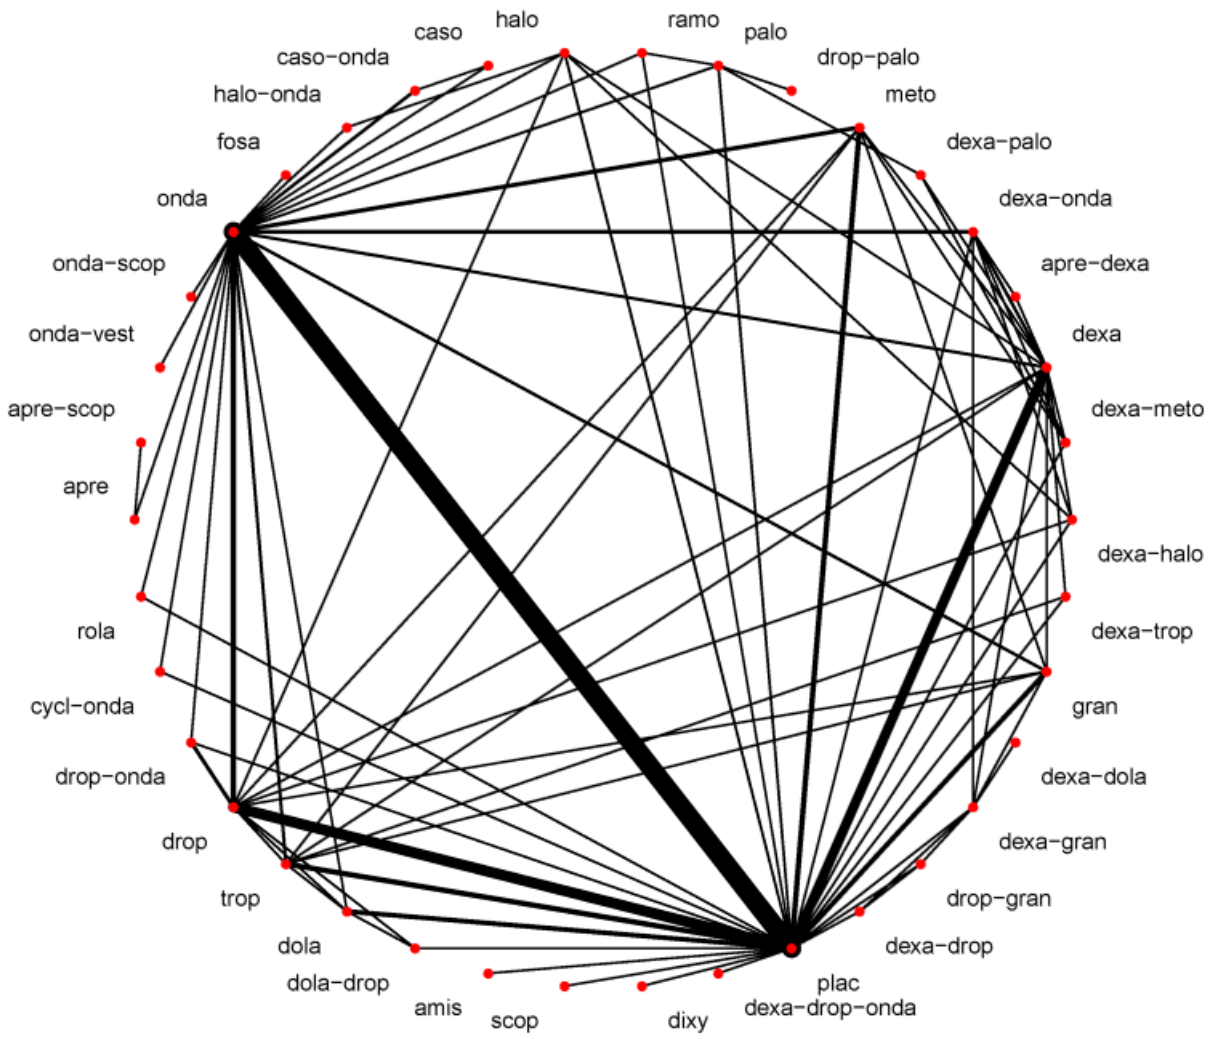
Figure 36. Network geometry of eligible comparisons for complete response within 24 hours postoperatively. The thickness of the edges is proportionate to the number of included studies comparing two treatments. Abbreviations for treatments correspond to the first four letters of the drug name and are listed in the Methods and in Appendix 6.



For 38 different treatments, 703 pair-wise comparisons are possible, and the results of all network estimates are available in the online repository. For 76 of 703 comparisons, direct and indirect evidence was available, whereas for 13 comparisons, only direct evidence was available, and for 614 comparisons, only indirect evidence was available.

The relative efficacy presented as summary relative effects (RR with 95% CI) of all drugs or drug combinations compared to placebo (reference compound) ranked according to P scores is shown in Figure 37. In terms of complete response, of the 17 single drugs, 11 showed important benefit (95% CI lower boundary > 1.25) compared to placebo, with RRs ranging between 2.23 (95% CI 1.68 to 2.96) for ramosetron and 1.45 (95% CI 1.29 to 1.64) for dolasetron. Amongst the most effective single drugs of direct interest with important benefit for complete response compared to placebo in increasing order according to P scores were ramosetron, granisetron, fosaprepitant, aprepitant, palonosetron, dexamethasone, haloperidol, tropisetron, droperidol, ondansetron, and dolasetron. Five single drugs, four of direct interest (scopolamine, casopitant, rolapitant, amisulpride), showed benefit associated with uncertainty (95% CI crossing the range of equivalence). One single drug of direct interest (metoclopramide) showed little or

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

no effect associated with uncertainty (95% CI crossing the range of equivalence). Treatment effects of all single drugs compared to placebo ranged between RR 11.00 (95% CI 0.64 to 188.18) for scopolamine and RR 1.23 (95% CI 1.06 to 1.43) for metoclopramide. Of the 20 drug combinations, 16 combinations showed important benefit compared to placebo, with RRs ranging between 2.81 (95% CI 1.59 to 4.96) for cyclizine-ondansetron and 1.61 (95% CI 1.31 to 1.97) for dexamethasone-metoclopramide. Four drug combinations showed benefit associated with uncertainty compared to placebo. Treatment effects of drug combinations compared to placebo ranged between RR 2.81 (95% CI 1.59 to 4.96) for cyclizine-ondansetron and RR 1.49 (95% CI 0.93 to 2.37) for aprepitant-scopolamine.

Figure 37. Forest plot of network meta-analysis of all trials for complete response within 24 hours postoperatively. Single drugs and combinations were compared with placebo (reference compound). RR = risk ratio, 95% CI = 95% confidence interval. RR > 1 favours the intervention, RR < 1 favours placebo. The blue lines indicate the range of

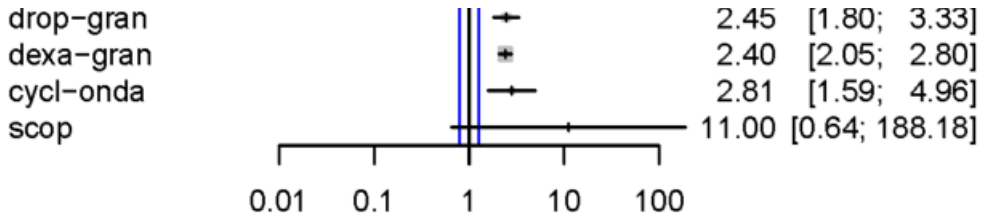
Figure 37. (Continued)



The estimated value of between-study variance for the network meta-analysis of complete response was 0.0196 (tau²) (I^2 = 47.8%). For the random-effects model, there was heterogeneity within designs (Q = 146.39, df = 76, P < 0.0001) and inconsistency between designs (Q = 163.83, df = 86, P < 0.0001). When the full random-effects design-by-treatment interaction model was used, there was no evidence of residual statistical inconsistency (Q = 84.96, df = 86, P = 0.51). Clinically relevant heterogeneity for comparisons of direct interest (single drugs of direct interest compared to placebo) was detected for aprepitant, dexamethasone, dolasetron, droperidol, fosaprepitant, haloperidol, ondansetron, palonosetron, and tropisetron. In these cases, 95% PIs of treatment estimates included different clinical implications compared to the 95% CIs. Splitting of direct and indirect evidence in the network meta-analysis and testing for local inconsistency revealed disagreement (direct versus indirect) for four out of 76 comparisons (dexamethasone versus dexamethasone-palonosetron (P = 0.04), dexamethasone versus placebo (P = 0.008), dexamethasone-palonosetron versus palonosetron (P = 0.03), palonosetron versus placebo (P = 0.04)). Clinically relevant incoherence of direct and indirect treatment estimates for single drugs of direct interest compared to placebo was found for dexamethasone, ondansetron, palonosetron, and tropisetron.

Reporting bias (complete response)

Three direct pair-wise comparisons included 10 or more studies for which small-study effects such as reporting or publication bias were investigated: dexamethasone, droperidol, and ondansetron, all compared to placebo. Results of the funnel plots, the arcsine test for funnel plot asymmetry, and the trim and fill sensitivity analysis are presented in the online repository. According to the explorative analyses, we suspected publication bias for the comparisons droperidol versus placebo (P = 0.10) and ondansetron versus placebo (P = 0.01). The contour-enhanced funnel plots also suggested asymmetry for dexamethasone versus placebo. However, we did not suspect relevant publication bias for this comparison because trim and fill sensitivity analysis did not change the conclusion with respect to the range of equivalence. Asymmetry may have been caused by other factors such as heterogeneity.

DISCUSSION

Summary of main results

This systematic review with network meta-analyses investigated the efficacy and safety of drugs for prevention of postoperative nausea and vomiting (PONV) with focus on postoperative vomiting in adults after general anaesthesia. It included 585 randomized controlled trials (RCTs) with 97,516 participants. A total of 44 single antiemetic drugs belonging to six different substance classes (5-HT_3 receptor antagonists, D_2 receptor antagonists, NK_1 receptor antagonists, corticosteroids, antihistamines, and anticholinergics) and 51 drug combinations were investigated. An overview of the direction and magnitude of effects along with the certainty of evidence for all GRADE-relevant outcomes and all single drugs of direct interest, according to Gan 2014, compared to placebo is summarized in Figure 7.

Primary outcomes

The network meta-analysis (NMA) of the primary efficacy outcome 'vomiting within 24 hours postoperatively' included 282 RCTs, 50,812 participants, and 65 interventions. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to high. High-certainty evidence showed that five drugs (aprepitant, ramosetron, granisetron, dexamethasone, and ondansetron) reduced vomiting, and moderate-certainty evidence indicated that another two single drugs (fosaprepitant and droperidol) probably reduced vomiting compared to placebo (Summary of findings 1; Summary of findings 2). These are the seven most reliable and most effective drugs identified in this review for 'vomiting within 24 hours postoperatively'. All other single drugs of direct interest involved evidence of very low to low certainty (casopitant, tropisetron, and dolasetron), or they were less effective (amisulpride and promethazine), or both (palonosetron, haloperidol, metoclopramide, rolapitant, dimenhydrinate, and scopolamine). In the ranking of treatments with placebo as comparator, single drugs of direct interest with decreasing order according to efficacy were fosaprepitant, casopitant, aprepitant, ramosetron, granisetron, dexamethasone, tropisetron, dimenhydrinate, promethazine, rolapitant, ondansetron, dolasetron, haloperidol, scopolamine, droperidol, palonosetron, amisulpride, and metoclopramide. Drug combinations were generally more effective than most of the single drugs. However, treatment effects of the top three ranked

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

single drugs, which belong to the NK_1 receptor antagonist class (fosaprepitant, casopitant, and aprepitant), were comparable to most of the included drug combinations.

The certainty of evidence for single drugs of direct interest in preventing postoperative vomiting applies to recommended and high doses of granisetron, ondansetron, dexamethasone, droperidol, and tropisetron because low doses showed no clinically important effect. Recommended and high doses of these drugs showed similar treatment effects. Thus, recommended doses should be sufficient to prevent postoperative vomiting (Table 3). For all other single drugs of direct interest, there was no clinically relevant difference between the analysed dose categories. Therefore we are best advised to use the most investigated dose, route, and timing of individual drugs as the most reliable current guide (Table 3).

The NMA of the primary safety outcome 'number of participants with SAEs within seven days postoperatively' included 28 RCTs, 10,766 participants, and 22 interventions. A large number of trials (41%) have reported zero events in all study arms, and the baseline risk for serious adverse events (SAEs) with placebo was 1.43%. Only three single drugs of direct interest (aprepitant, dolasetron, and palonosetron) were investigated in large RCTs (> 500 participants/treatment). Thus, the chance to detect rare SAEs was highest for aprepitant, dolasetron, and palonosetron. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to low (Summary of findings 1; Summary of findings 3). In terms of treatment effects, none of the active treatments showed important harm or benefit compared to placebo, and all were associated with uncertainty. In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of SAEs were dolasetron, tropisetron, palonosetron, amisulpride, droperidol, ramosetron, scopolamine, dexamethasone, granisetron, aprepitant, ondansetron, and casopitant. Treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty.

The NMA of the primary safety outcome 'number of participants with any AE [adverse event] within seven days postoperatively' included 61 RCTs, 19,423 participants, and 27 interventions. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to moderate (Summary of findings 1; Summary of findings 4). Moderate-certainty evidence shows that granisetron and amisulpride probably had no or little effect on any AE compared to placebo. Two of the 14 single drugs of direct interest, namely, dimenhydrinate and scopolamine, have low-certainty evidence and may increase the number of participants with any AE compared to placebo. None of the other single drugs of direct interest showed important harm. All showed benefit or no effect, but all were associated with only low- or very low-certainty evidence. In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of any AE were dexamethasone, aprepitant, dolasetron, casopitant, droperidol, granisetron, metoclopramide, ondansetron, palonosetron, ramosetron, amisulpride, tropisetron, scopolamine, and dimenhydrinate. Of all drug combinations, only ondansetron-scopolamine showed important benefit for any AE compared to placebo. No combinations showed important harm. However, caution is advised, as we have not assessed the certainty of evidence for any of the drug combinations. Treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty. However, in the ranking of treatments, high and recommended doses generally ranked higher than lower doses of the individual drugs in terms of favourable effects on any AE. Thus, contrary to the intuitive assumption that lower doses of drugs produce fewer side effects than higher doses, the opposite seems to be the case here. These findings could be explained by the fact that prevention of PONV generally lowers the risk of other adverse effects (Kranke 2018). Some molecules directly prevent adverse effects, such as headache when droperidol is used, or act as co-analgesics (e.g. valid for dexamethasone).

Secondary outcomes

Substance class-specific side effects

The most investigated secondary safety outcome was headache, with 208 RCTs, 42,445 participants, and 53 interventions. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to moderate (Summary of findings 1; Summary of findings 5). Moderate-certainty evidence shows that droperidol probably reduces and ondansetron probably increases headache—both compared to placebo. None of the other single drugs of direct interest showed important benefit or harm, and all treatment effects were associated with uncertainty, resulting in only low or very low certainty of evidence. However, a tendency toward the well-known substance class-specific increase in headache for $5\text{-}HT_3$ receptor antagonists showed up in the NMA (https://en.wikipedia.org/wiki/5-HT3_antagonist). In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of headache were haloperidol, promethazine, droperidol, casopitant, dexamethasone, aprepitant, metoclopramide, scopolamine, dimenhydrinate, tropisetron, dolasetron, ramosetron, palonosetron, ondansetron, granisetron, and amisulpride. Of all drug combinations, only droperidol-tropisetron showed important benefit for headache compared to placebo. None showed important harm. However, caution is advised because we have not assessed the certainty of evidence for any of the drug combinations. Treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty. However, in the ranking of treatments at different doses, a similar tendency of drug doses was detectable as was found for any AE. Higher doses of drugs produce fewer headache than lower doses.

The secondary safety outcome sedation included 117 RCTs, 21,440 participants, and 44 interventions. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to high (Summary of findings 1; Summary of findings 6). High-certainty evidence shows that dexamethasone has no or little effect on sedation compared to placebo. Moderate-certainty evidence indicates that dimenhydrinate probably increases sedation and ondansetron probably reduces sedation—both compared to placebo. None of the other single drugs of direct interest showed important benefit or harm, and all were assessed with only low- or very low-certainty evidence. In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of sedation were perphenazine, tropisetron, ondansetron, aprepitant, ramosetron, haloperidol, metoclopramide, droperidol, amisulpride, dolasetron,

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

granisetron, dexamethasone, promethazine, palonosetron, scopolamine, methylprednisolone, and dimenhydrinate. Of all drug combinations, only dexamethasone-metoclopramide showed an important reduction in sedation, and dimenhydrinate-ondansetron showed an important increase in sedation—both compared to placebo. However, caution is advised because we have not assessed the certainty of evidence for any of the drug combinations. According to dose, a clinically relevant difference between doses was found only for high and recommended doses of ondansetron compared to low doses. High and recommended doses probably reduced sedation, and low doses increased sedation. All other treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty.

The secondary safety outcome extrapyramidal symptoms included 64 RCTs, 10,724 participants, and 30 interventions. A large number of trials (75%) have reported zero events in all study arms, and the baseline risk for extrapyramidal symptoms with placebo was 0.79%. Only droperidol was investigated in a large RCT (> 500 participants/treatment). Thus, the chance to detect rare extrapyramidal symptoms was highest for droperidol. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to low (Summary of findings 1; Summary of findings 7). In terms of treatment effects, none of the active treatments showed important harm or benefit compared to placebo, and all were associated with uncertainty. However, a tendency of the well-known substance class-specific increase in extrapyramidal symptoms for D_2 receptor antagonists showed up in the NMA (https://en.wikipedia.org/wiki/Dopamine_antagonist). The currently best D_2 receptor antagonist with no or minimal effect seems to be amisulpride. In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of extrapyramidal symptoms were ondansetron, dexamethasone, dolasetron, tropisetron, ramosetron, granisetron, palonosetron, amisulpride, perphenazine, metoclopramide, haloperidol, and droperidol. Treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty.

The secondary safety outcome constipation included 43 RCTs, 11,481 participants, and 23 interventions. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to low (Summary of findings 1; Summary of findings 8). In terms of treatment effects, none of the active treatments showed important harm or benefit compared to placebo, and all were associated with uncertainty. In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of constipation were granisetron, ramosetron, casopitant, dexamethasone, ondansetron, aprepitant, palonosetron, tropisetron, amisulpride, and metoclopramide. Treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty.

The secondary safety outcome postoperative wound infection included 32 RCTs, 4369 participants, and 10 interventions. A large number of trials (80%) have reported zero events in all study arms, and the baseline risk for postoperative wound infection with placebo was 0.44%. Most information was available for dexamethasone, but none of the studies investigating dexamethasone or any other drug was of sufficient size (> 500 participants/treatment). Thus, the chance to detect rare postoperative wound infections was strongly limited with this NMA. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to low (Summary of findings 1; Summary of findings 9). In terms of treatment effects, none of the active treatments showed important harm or benefit compared to placebo, and all were associated with uncertainty. In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of postoperative wound infection were tropisetron, methylprednisolone, metoclopramide, dexamethasone, and ondansetron. Treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty.

The secondary safety outcome arrhythmia included 25 RCTs, 5067 participants, and 18 interventions. A large number of trials (72%) have reported zero events in all study arms, and the baseline risk for arrhythmia with placebo was 4.25%. Only dolasetron and ondansetron were investigated in large RCTs (> 500 participants/treatment). Thus, the chance to detect rare postoperative arrhythmias was highest for dolasetron and ondansetron. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to low (Summary of findings 1; Summary of findings 10). In terms of treatment effects, none of the active treatments showed important harm or benefit compared to placebo, and all were associated with uncertainty. In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of arrhythmia were dolasetron, dexamethasone, droperidol, granisetron, tropisetron, methylprednisolone, haloperidol, metoclopramide, ondansetron, and ramosetron. All treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty.

The secondary safety outcome visual disturbances included 21 RCTs, 3634 participants, and 12 interventions. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to low (Summary of findings 11). In terms of treatment effects, scopolamine and the combination of ondansetron and scopolamine showed important harm compared to placebo. None of the other active treatments showed important harm or benefit compared to placebo, and all were associated with uncertainty. In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of visual disturbances were methylprednisolone, droperidol, dexamethasone, tropisetron, metoclopramide, ondansetron, and scopolamine. Treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty.

The secondary safety outcome QT prolongation included 18 RCTs, 4440 participants, and 13 interventions. A large number of trials (44%) have reported zero events in all study arms, and the baseline risk for QT prolongation with placebo was 2.12%. Only aprepitant was investigated in a large RCT (> 500 participants/treatment). Thus, the chance to detect rare postoperative QT prolongations was highest for aprepitant. The certainty of evidence for single drugs of direct interest compared to placebo ranged from very low to low (Summary of findings 1; Summary of findings 12). In terms of treatment effects, none of the active treatments showed important harm or benefit compared to

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

placebo, and all were associated with uncertainty. In the ranking of treatments with placebo as comparator, single drugs of direct interest in increasing order according to the risk of QT prolongation were palonosetron, ramosetron, dexamethasone, ondansetron, tropisetron, aprepitant, haloperidol, and droperidol. Treatment effects of different doses of single drugs did not differ in a clinically relevant manner and were associated with uncertainty.

Other secondary outcomes

We have investigated five other secondary outcomes, including mortality within seven days, along with the efficacy outcomes of early and late vomiting, nausea, and complete response within 24 hours. We have not assessed the certainty of evidence for drugs included in the NMAs of these outcomes.

Mortality was reported in only 17 RCTs including 6840 participants. Only one participant with ondansetron died during the study period, and study authors reported that the participant´s death was not drug-related.

The efficacy profile of the seven most effective and most reliable single drugs for the primary outcome 'vomiting within 24 hours' (fosaprepitant, aprepitant, ramosetron, granisetron, dexamethasone, ondansetron, and droperidol) showed a slightly different efficacy profile for other efficacy outcomes such as vomiting (early and late), nausea, and complete response compared to the primary outcome. For early vomiting, the benefit of aprepitant was associated with uncertainty, and the treatment effect of droperidol was slightly better for vomiting within 24 hours, which was comparable to the other 5-HT_3 receptor antagonists. Treatment effects of fosaprepitant, granisetron, ramosetron, ondansetron, and dexamethasone were comparable for early vomiting and vomiting within 24 hours. For late vomiting, no studies investigated fosaprepitant. Aprepitant was the most effective drug for late vomiting. Aprepitant, granisetron, and ramosetron were more effective compared to early vomiting and vomiting within 24 hours. The treatment effect of droperidol was associated with uncertainty and was slightly worse for early vomiting and vomiting within 24 hours. Dexamethasone and ondansetron showed similar treatment effects at all time points investigated for vomiting. For nausea within 24 hours, treatment effects of the NK_1 receptor antagonists, fosaprepitant and aprepitant, were associated with uncertainty and showed less benefit than for vomiting. Ramosetron, droperidol, granisetron, dexamethasone, and ondansetron all showed similarly important benefit for nausea, and their anti-nausea efficacy was comparable to antiemetic efficacy. For the composite outcome ‘complete response’, all seven drugs showed important benefit and were ranked in decreasing order according to efficacy as ramosetron, granisetron, fosaprepitant, aprepitant, dexamethasone, droperidol, and ondansetron.

Overall completeness and applicability of evidence

Types of participants

Most of the studies in the current review included participants at moderate to high risk for PONV based on patient-specific, anaesthesia- and surgery-related risk factors. Most participants were women (83%), received perioperative opioids (88%), were undergoing general anaesthesia using volatile anaesthetics (88%), and were subject to gynaecological or gastrointestinal surgery (53%). The results of the review have limited external validity with respect to the broad population of adults undergoing any surgery with general anaesthesia but are directly transferable to patients at risk for PONV (i.e. women undergoing gynaecological/gastrointestinal surgery with volatile anaesthesia and with the use of perioperative opioids). External validity is further limited in that a majority of trials were conducted in inpatient settings and included healthy participants classified as American Society of Anesthesiologists status ASA I and II (70%). There was at least some geographic variation in study locations, but most of the studies were conducted in Asia (51%), Europe (25%), and North America (16%).

Outcomes

We have chosen vomiting instead of nausea as the primary outcome for this review because vomiting is an objectively measurable outcome and may be associated with higher risk of complications for the postoperative patient compared to nausea. Nevertheless, several other PONV outcomes such as nausea and complete response were also examined as secondary outcomes in this review. However, depending on the outcome of interest, there should be an altered risk/benefit assessment of some antiemetics due to different effect profiles. For example, NK_1 receptor antagonists have a better effect against vomiting than against nausea and therefore do better in this review with a focus on vomiting. In general, the main focus of this review should be on the side effects of antiemetics, as the benefits of antiemetics have been reported much better in the community than their side effects.

Efficacy

With this review, we found sufficient available information to address the review questions on efficacy of antiemetic drugs for prevention of vomiting within 24 hours postoperatively. We found high-certainty evidence showing that five single drugs (aprepitant, ramosetron, granisetron, dexamethasone, and ondansetron) reduce vomiting, and moderate-certainty evidence indicating that two other single drugs (fosaprepitant and droperidol) probably reduce vomiting compared to placebo. Consequently, four of the six substance classes (5-HT_3 receptor antagonists, D_2 receptor antagonists, NK_1 receptor antagonists, and corticosteroids) were represented by at least one single drug with high or moderate certainty of evidence and important benefit for prevention of vomiting. In absolute numbers, for 1000 patients, of whom 300 would vomit after surgery if given placebo, 282 would benefit from fosaprepitant (the most effective drug of the seven most reliable single drugs) and 18 would not, or 117 would benefit from droperidol (the least effective drug of the seven most reliable single drugs) and 183 would not.

Safety and adverse events

In contrast to the large number of studies (89%) reporting relevant efficacy outcomes for this review, just over half of all studies (56%) reported at least one relevant safety outcome. Thus, relevant safety outcomes were highly underrepresented in the included studies. Furthermore, we could not exclude a certain risk of bias, as side effects may be prone to selective outcome reporting and may have been reported more frequently when the findings were generally positive. In this NMA, the risk of selective outcome reporting was difficult to assess, as we found few studies with a prospectively registered protocol. In addition, most of the investigated side effects occurred at a lower rate compared to the rate of PONV (with the exception of the composite safety outcome ‘any AE’, which

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

has a similar incidence (38%) in placebo-treated participants after surgery under general anaesthesia as postoperative vomiting in the current review). In general, the lower the event rate, the higher the need for a larger number of study participants to overcome the imprecision of meta-analytic results and to increase the chance of detecting rare events. The most investigated specific side effects in this review were headache (with 208 studies) and sedation (with 117 studies), both with incidences of about 10% in the placebo group. Other side effects were investigated to a much lesser extent and with a much lower baseline risk with placebo. Besides, most of the studies included in NMAs of rare outcomes were small and, therefore, have been unable to detect rare events. Finally, most of the NMA treatment effects were imprecise, which was reflected by only very low- to low-certainty evidence. However, rare adverse effects may be observed only in non-randomized studies such as large cohort studies or case-control studies (Higgins 2019). Therefore, future studies or systematic reviews on adverse events of antiemetic drugs should be or should include non-randomized studies, respectively.

There were two additional issues with adverse events. First, a detailed definition of adverse outcomes such as QT prolongation by study authors often was not available, was difficult to assess, or was different between studies. In addition, the composite outcome 'any AE' was most often given as the total number of participants with any adverse events. However, a detailed definition of which outcomes were finally included often was not provided. Therefore, the separated individual side effects such as headache were more specific and informative. Second, study authors reporting the composite outcome 'any AE' often gave insufficient information on the method of monitoring adverse events. In most studies, it is unclear whether researchers have actively surveyed participants and have asked for the occurrence of any adverse event, or whether they have used only information derived from routinely assessed patient records or have focused only on specific adverse events, lacking relevant side effects.

Interventions

This review compared 44 single drugs belonging to six different substance classes. Twenty-one of the 44 drugs were of direct interest, all of which are listed in the consensus guidelines for management of postoperative nausea and vomiting (Gan 2014), with exception of the two newer drugs, fosaprepitant and amisulpride. An additional 23 drugs were not of direct interest and were used only to supplement the analysis. Drugs not of direct interest were investigated in only 7% of all included studies, limiting the gain of additional information and reflecting the lack of importance of these drugs in clinical practice. The current review is clearly dominated by three single drugs of direct interest: ondansetron (with 246 studies), dexamethasone (with 120 studies), and droperidol (with 97 studies). Of the 21 single drugs of direct interest, only meclizine was not investigated as a single drug for any of the outcomes of interest. It was investigated only in combination with ondansetron. Methylprednisolone and perphenazine, used as single drugs, were not investigated for the primary outcome of vomiting. Fosaprepitant and rolapitant were not investigated for any of the relevant safety outcomes. Dexamethasone, ondansetron, and tropisetron were present in all outcomes investigated in this review. Finally, on the level of substance classes, the 5-HT_3 receptor antagonists were the largest and the best investigated substance class in this review.

Included studies were published between 1965 and 2017. However, most included studies (71%) were published in the last two decades between 2000 and 2017. Despite the large amount of information reported from clinical trials on this topic, the flood of clinical trials was increasing over time, reaching a peak in 2007 with 36 published trials. Since 1996, more than 15 study reports per year were published (Figure 4). On the one hand, there were new substances, such as amisulpride and fosaprepitant, which have been investigated only in recent trials. On the other hand, there were several old and well-known drugs, such as ondansetron, dexamethasone, and droperidol, that have been used extensively in previous studies. However, they have also been studied in recent studies. The use of ondansetron, the gold standard in PONV clinical trials, has its justification in newer studies as an active comparator. However, other recent studies—Zhang 2013-1; Zhang 2013-2—compared ondansetron against placebo and provided no new or additional valuable findings compared to the large IMPACT trial published in 2004 (Apfel 2004-1; Apfel 2004-2). Studies that investigate what we already know and do not add any clinically relevant information are not useful and should be avoided (Ioannidis 2016).

Combination therapy

Combination therapy for PONV prophylaxis is preferable to use of single drugs alone in patients at moderate risk (Gan 2014). Ondansetron, dexamethasone, and droperidol, for example, have similar efficacy for PONV prophylaxis and, when used in combination, they showed additive effects due to independent mechanisms of action (Apfel 2004-1; Apfel 2004-2). In this review, in addition to single drugs, any drug combination was included, and this resulted in the inclusion of 51 different drug combinations. In total, 28% of studies included drug combinations and 72% of all studies investigated single drugs only. Thus, evidence for the effectiveness of drug combinations in this review was based on substantially fewer studies than for single drugs alone. Nevertheless, 29 (81%) of 36 drug combinations investigating the prevention of vomiting within 24 hours showed important treatment effects based on NMA. Dexamethasone-ondansetron (in 54 studies), dexamethasone-granisetron (in 20 studies), and droperidol-ondansetron (in 15 studies) are the only drug combinations included in this review that were investigated in more than 10 studies. Testing the additivity assumption for prevention of vomiting within 24 hours revealed additive effects of single drugs for these three combinations. Altogether, all three combinations were equally effective in preventing vomiting within 24 hours, with comparable effectiveness to aprepitant administered as a single drug.

Combination treatments should include drugs of different substance classes with different mechanisms of action (Gan 2014). This recommendation is based on a strong biological rationale without proof in clinical studies, as combinations of drugs from the same substance class were not investigated in practice. Besides this biological rationale, several findings on NMA treatment effects for other efficacy outcomes (e.g. nausea) and adverse effects of single drugs supported the use of combinations of drugs from different substance classes. First, the NK_1 receptor antagonists showed promising antiemetic efficacy, whereas anti-nausea efficacy was less prominent and was associated with uncertainty. In contrast, the 5-HT_3 receptor antagonists ramosetron and granisetron and the D_2 receptor antagonist droperidol effectively reduced nausea. Therefore, ramosetron, granisetron, and droperidol might

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

compensate for the reduced anti-nausea effects of NK_1 receptor antagonists. Second, 5-HT_3 receptor antagonists increased the incidence of headache, whereas the D_2 receptor antagonist droperidol reduced the incidence of headache. A combination of droperidol and ondansetron had an additive effect in reducing postoperative vomiting and might also have reduced the incidence of headache. However, caution is advised because the certainty of evidence was not assessed for other efficacy outcomes nor for combinations of drugs.

Applicability of doses, administration routes, and application time points

For the primary network meta-analyses, different doses, administration routes, and application time points of individual drugs were pooled together. Administration routes and application time points were recorded in the Characteristics of included studies section but were not analysed in detail in this review. Dose effects were investigated in a subgroup analysis for vomiting, splitting doses of drugs into dose categories in accordance with current recommendations (Gan 2014). This review shows that low doses of granisetron, ondansetron, dexamethasone, droperidol, and tropisetron were less effective compared to recommended and high doses. Because recommended and high doses of these drugs were similarly effective, we assume recommended doses to be sufficient to prevent vomiting. No dose effects were detectable for the other drugs, and we are best advised to use the most investigated doses of drugs as the most reliable current guide. With respect to recommendations of the current guideline, casopitant, palonosetron, ramosetron, rolapitant, and tropisetron were most often used at recommended doses according to Gan 2014 in this systematic review. However, most of the studies investigating aprepitant, dolasetron, haloperidol, and promethazine used high doses, and most of the studies investigating dimenhydrinate and metoclopramide used low doses. In these cases, dose recommendations should be reconsidered, or additional studies should investigate dose effects of these drugs. Ongoing debate focuses on the topic of whether metoclopramide is effective for prevention of PONV and whether its limited effectiveness may be caused by low dosing schemes (DeOliveira 2012; Wallenborn 2006). For amisulpride, fosaprepitant, and scopolamine, the current guidelines did not give any dose recommendations (Gan 2014). In the current systematic review, amisulpride was most often used at a dose of 5 mg (IV, at induction of anaesthesia), fosaprepitant at 150 mg (IV, at induction of anaesthesia), and scopolamine at 1.5 mg (TD, at induction of anaesthesia).

Interventions in current practice

The seven most effective single drugs for prevention of postoperative vomiting with at least moderate-certainty evidence found in this review vary by the level of establishment and use in current practice. Ondansetron is the most used gold standard antiemetic drug worldwide developed in the 1980s and approved by the US FDA since January 1991. Dexamethasone was developed in 1957 and was approved for medical use in 1961. It is listed together with ondansetron and metoclopramide as an antiemetic medicine in the World Health Organization List of Essential Medicines reporting the most effective and safe medicines needed in a health system (WHO Model List of Essential Medicines 2019). Droperidol was developed in the 1950s as an antipsychotic and was first approved in Denmark in 1963 for use in anaesthesia, PONV, and psychiatry. In the United States, droperidol was withdrawn from clinical use in 2001 (FDA black box warning) due to accumulating evidence of QT prolongation and concerns about the risk of torsades de pointes (Sneyd 2009). Recently it has been re-licensed in Europe for prevention and treatment of PONV at lower doses of 0.625 to 1.25 mg in adults, and for prevention of nausea and vomiting during postoperative patient-controlled analgesia (PCA) in adults. Granisetron was developed in 1988 and was approved in the UK in 1991 and in the United States in 1994 by the FDA. Ramosetron is approved for use only in Japan and in certain Southeast Asian countries for treatment of nausea and vomiting and diarrhoea-predominant irritable bowel syndrome in males (https://www.drugbank.ca/drugs/DB09290). Aprepitant was approved for medical use in Europe and the United States in 2003. It is listed on the complementary list of antiemetic medicines in the World Health Organization List of Essential Medicines (WHO Model List of Essential Medicines 2019). Fosaprepitant was approved in 2008 by the FDA for use in combination with other antiemetics for prevention of nausea and vomiting caused by chemotherapy. Unlike aprepitant, fosaprepitant is approved by the FDA for prevention of PONV.

Quality of the evidence

Certainty of evidence

This review includes a large number of studies (585 RCTs and 97,516 participants) with a large number of interventions (44 single drugs and 51 drug combinations). Grading the certainty of evidence for all possible combinations of interventions would be difficult to conduct in a reasonable time frame and would be challenging to present in an accessible manner. As an example, for vomiting within 24 hours with 65 different treatments, a total of 2080 pair-wise combinations of treatments were possible. This would equate to 2080 evaluations of the certainty of evidence, which would be an almost unmanageable task and would yield an overload of information. Therefore, we decided to limit the assessment of the certainty of evidence to single drugs of direct interest compared to placebo. As a limitation of this review, an assessment of the certainty of evidence for all drug combinations and all active comparisons is not available.

Study quality based on risk of bias assessments

The overall methodological quality of the primary studies assessed by the Cochrane risk of bias assessment tool 1.0 was limited (Higgins 2011). Only 27% of the studies were assessed as having overall low risk of bias. Most of the studies completely reported their outcome data, which was feasible due to the short follow-up intervals of the study. Major quality concerns were related to selection bias, performance and detection bias, reporting bias, and the other bias domain. About half of all studies did not report the method used for randomization, and 88% of the studies did not specify how allocation of participants was concealed to recruiters. Blinding of participants, personnel, and outcome assessors was not sufficiently described in about 40% of all studies, and about 10% had a non-blinded study design. Selective outcome reporting could be assessed only for studies that had published a prospectively registered study protocol. In total, only 5% of all included studies had a prospectively registered study protocol, and only 2% were judged to have low risk of selective outcome reporting. In the end, we used information from the risk of bias assessment for sensitivity analyses and interpretation of the certainty of evidence for all relevant outcomes. For vomiting within 24 hours, sufficient studies

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

at low risk of bias were available to yield a robust NMA treatment effect estimate for at least seven effective single drugs, with high- or moderate-certainty evidence (aprepitant, ramosetron, granisetron, dexamethasone, ondansetron, fosaprepitant, and droperidol). For other safety outcomes, limited study quality was a frequent reason for downgrading the certainty of evidence.

Imprecision

For the primary efficacy outcome postoperative vomiting within 24 hours, high-certainty evidence shows that five single drugs (aprepitant, ramosetron, granisetron, dexamethasone, and ondansetron) reduce vomiting, and moderate-certainty evidence indicates that two other single drugs (fosaprepitant and droperidol) probably reduce vomiting compared to placebo. For most of the primary (SAE, any AE) and secondary safety outcomes (headache, sedation, extrapyramidal symptoms, constipation, wound infection, arrhythmia, QT prolongation, and visual disturbances), we found only very low- to low-certainty evidence for the effects of single drugs of direct interest compared to placebo. Only a few exceptions are listed under Summary of main results. One of the main reasons for the different certainty of evidence levels for drugs in terms of efficacy and safety outcomes was the different amount of underlying information in the NMAs (studies and participants) combined with the lower baseline risks of most safety outcomes. Therefore, the certainty of evidence for safety outcomes is limited for most single drugs of direct interest as a result of imprecision.

We used a clinically relevant size of effects—not statistical significance—to describe and interpret network meta-analysis estimates (Nikolakopoulou 2019; Wasserstein 2019). A risk ratio (RR) of 0.8, which is equivalent to a relative risk reduction (RRR) of 20%, was assumed as a clinically relevant effect for vomiting, and an RR of 0.9 (RRR 10%) was assumed as a clinically relevant effect for all side effects. It is an advantage that precise effect estimates, which are small (and clinically not relevant) but statistically significant in a traditional sense, were not necessarily classified as having a relevant effect. If such small and precise effect estimates were located in the range of equivalence (RR 0.8 to 1.25 for vomiting), they were classified as clinically not important. Only effect estimates that were completely below an RR of 0.8 (benefit) or above an RR of 1.25 (harm) were considered clinically relevant. Moreover, intermediate stages of effect estimates might allow an interpretation of imprecision reflecting the uncertainty associated with effect estimates when 95% confidence intervals (CIs) are broad and include different ranges. Furthermore, retiring statistical significance and focusing on clinically relevant effect sizes helps to solve issues associated with multiple testing in NMA (Efthimiou 2019).

Indirectness

All studies included in this review were relevant for the research question in terms of our defined population, interventions, comparisons, outcomes, and settings of interest. Our PICO criteria are very specific, and all of the conclusions that we have drawn in this review have been directly related to our research question. Consequently, there were no concerns of indirectness in this review, and the certainty of evidence was not downgraded for this item. However, the CINeMA (Confidence in Network Meta-Analysis) approach further considers an imbalance in the distribution of effect-modifying variables among different comparisons for the assessment of indirectness (Nikolakopoulou 2019; Salanti 2014). Effect modifiers are characteristics that impact the relative treatment effect. Comparisons in NMAs will provide direct evidence only if effect modifiers are equally distributed across studies and comparisons. In this case, the assumption of transitivity holds in the NMA. In the protocol, we defined differences in sources of funding, differences in risk of bias, and differences in details of the interventions as effect-modifying variables relevant for this review. In contrast, risk factors for PONV are prognostic variables that directly affect the outcome but not the relative treatment effect on the outcome. In the final review, we accepted heterogeneity (see inclusion criteria of this review) for the effect modifiers 'risk of bias' and 'dose of intervention'. We have, however, assessed the impact of these effect modifiers in sensitivity analyses (risk of bias) and subgroup analyses (dose). Due to the quantity of data and the lack of information for the effect modifier 'funding source' in many studies, an objective and reliable assessment of the distribution of this effect modifier within all comparisons was not possible. In general, we assumed that for all included studies, the study populations, interventions, outcomes, and study settings matched the inclusion criteria of the current systematic review and were sufficiently similar. We have, however, accepted heterogeneity for risk of bias and for intervention details. Thus, we concluded that there was no relevant clinical and methodological heterogeneity within and across treatment comparisons (intransitivity) in the current review.

Heterogeneity and inconsistency/incoherence

In the entire network, there was heterogeneity within designs for the primary efficacy outcome of vomiting. For all other safety outcomes, no heterogeneity between studies of individual comparisons was detectable. At the level of individual comparisons of direct interest (single drugs of direct interest compared to placebo), we assessed heterogeneity using the 95% prediction interval (PI) and considered the impact on clinical conclusions (Nikolakopoulou 2019). In the case of heterogeneity, we investigated the effect-modifier dose in a subgroup analysis and accepted a clinically relevant difference between doses as an explanation for heterogeneity. If there was no explanation by different doses of the intervention, we downgraded due to heterogeneity. In the case of vomiting, heterogeneity was detectable for comparisons of ondansetron, tropisetron, dolasetron, droperidol, amisulpride, and dexamethasone—all compared to placebo. Recommended and high doses of ondansetron, droperidol, and dexamethasone were more favourable compared to low doses. Thus, the certainty of evidence for these comparisons could be applied only to recommended and high doses. Most of the comparisons included in safety outcomes appeared not heterogeneous, as the imprecision of effect estimates was already large.

In the entire network, there was inconsistency between designs for the primary efficacy outcome of vomiting. However, the full random-effects design-by-treatment interaction model revealed that there was no evidence of residual statistical inconsistency, which means that all interventions behave similarly in all comparisons. Other safety outcomes showed no inconsistency between designs. At the level of individual comparisons of direct interest (single drugs of direct interest compared to placebo), we assessed incoherence by comparing direct and indirect effect estimates with respect to impact on the clinical conclusion (Nikolakopoulou 2019). In cases where both estimates have

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

resulted in different conclusions, we downgraded this comparison for incoherence. Additionally, we performed a local test using a descriptive Z-statistic for incoherence. Results were reported in the Effects of interventions section, but results were not used for interpretation of incoherence due to the low power of the test.

Publication bias

Publication bias was investigated by explorative analyses for direct comparisons when 10 or more studies were included. Results of the explorative analyses were difficult to interpret because assessment of funnel plots is in general highly subjective, tests for funnel plot asymmetry have low power, and several factors other than publication bias may cause asymmetry in funnel plots. With respect to these limitations, we decided to assume a clinically relevant publication bias if the trim and fill sensitivity analysis changed the clinical conclusion. The trim and fill sensitivity analysis hypothetically estimates the effect based on missing information of the asymmetrical studies. For the primary outcome of vomiting, publication bias was suspected only for droperidol for all single drugs of direct interest compared to placebo. In the cases of dexamethasone, granisetron, and ondansetron (all compared to placebo), the contour-enhanced funnel plots also showed asymmetry. However, trim and fill did not change the conclusion. In cases of granisetron and ondansetron, although estimated effects were overestimated, they were still robust in terms of the range of equivalence. Other primary and secondary safety outcomes included too few studies to test for publication bias, and in cases with enough studies, no publication bias was suspected.

Ranking of treatments

We have reported ranking of treatments in terms of efficacy and safety. The ranking of treatments is based on P scores that measure the extent of certainty that a treatment is better than another treatment, averaged over all competing treatments (Rücker 2015). However, this statistical certainty should not be confused with certainty of evidence. In this review, we have not assessed the certainty of evidence for treatment rankings. In cases where a large number of parameters were independently estimated, the probability increases for finding some extreme results that do not reflect reality (Efthimiou 2019). Thus, the ranking of treatments should be interpreted with caution, and we want to avoid overstated claims. However, comparing the extent of an overlap of 95% CIs of different treatment comparisons may enable us to get a better idea of clinically relevant differences between interventions. In the case of vomiting with placebo as the reference compound, the NK_1 receptor antagonists (fosaprepitant, casopitant, and aprepitant) were the top three ranked single drugs of direct interest. They were comparably effective to most of the drug combinations, and their 95% CIs did not overlap with most of the other single drugs of direct interest. This is a strong indicator that NK_1 receptor antagonists are the most effective single drugs for prevention of vomiting. Differences between all other drugs are of minor importance. In case of most safety outcomes, the ranking of drugs is highly unreliable due to excessive uncertainty in the relative effects.

Potential biases in the review process

The feasibility of conducting an NMA including all available interventions to prevent PONV in adults after surgery strongly correlates with the number of included studies. At the protocol stage, we expected to include more than 1000 studies. Therefore, we carefully planned the best way to narrow down the inclusion criteria of this review to restrict the number of eligible studies in advance. We restricted the review to the population of adults undergoing general anaesthesia only, to pharmacological interventions with direct antiemetic action, and to randomized controlled trials published as full text. Thus we excluded all abstracts and conference proceedings (a total of 84 studies) from the current review. In a currently ongoing project, we used these excluded studies as well as further studies found in an additional search for abstract publications published in conference proceedings to assess the potential for the loss of this information (Hackenbroich (manuscript in preparation)). However, preliminary results indicated that eligibility of most of these abstracts (about 85%) cannot be classified due to missing information. Thus, poor reporting in abstract publications in the field of clinical PONV research seems to be a general limitation preventing inclusion into systematic reviews with narrow inclusion criteria. In contrast to the exclusion of abstract publications, we wanted to include all RCTs independent of their published language. In total, 83 (14%) of all included studies were not published in English. As a strength of this review, we included many local studies that were internationally conducted in non-English-speaking countries. Furthermore, we included full study reports that were not presented as a journal publication. Eligible studies were found in clinical trial registries, and full study reports were either directly linked or found on the companies' websites (e.g. GSK study register). Full study reports are highly valuable and contain detailed information on study details, especially safety assessments.

Several studies had duplicate publications in different journals and were listed in trial registries under different first authors; this complicated the process of data synthesis. By making the dataset fully and freely available, we welcome perusal by outside researchers to identify mistakes in our dataset, our analysis or our interpretation.

A total of 185 studies identified in the first search were listed as awaiting classification; these were either full-text publications (86 studies) or study protocols (99 studies). No full texts for screening and eligibility assessment could be retrieved for 29 studies. Insufficient reporting or lack of reporting of study details relevant for the inclusion/exclusion decision was the main reason for the inability to classify studies. Requests to study authors remained unanswered in these cases. In a worst-case scenario, if we assume that all 86 studies (awaiting classification) published as full text would have been eligible for this review, then we have currently lost about 10% of all available information to date due to poor reporting. However, about half of the studies published as full text and listed as awaiting classification were of older dates (date of publication before 2000). Therefore, we assume that inclusion of these studies would not have substantially altered the conclusions of this review. In contrast, the multitude of studies published only as study protocols and with pending classification were of later publication dates. Future inclusion of these studies could alter the conclusions of the review.

The review team conducting abstract and full-text screening, data extraction, and critical appraisal consisted of 11 persons with different background knowledge in conducting systematic reviews. We held several meetings and training sessions with review authors to ensure a comparable level of knowledge. All new Cochrane

Review authors had to complete the Cochrane online training (https://training.cochrane.org/interactivelearning). To reduce the risk of errors in data extraction and to reduce the risk of subjective differences in the critical appraisal, data extraction and critical appraisal of all included studies were further checked by one review author (SW, acting as a third author).

Agreements and disagreements with other studies or reviews

A MEDLINE search for 'postoperative nausea and vomiting' AND 'systematic review OR meta-analysis' revealed more than 500 records (November 2019). This snapshot of the literature showed not only that a large number of clinical trials have focused on PONV research but also that a relatively large number of systematic reviews have focused on this topic. In the following discussion, we limit the critical comparison of our most important findings to two large and well-known systematic reviews—the Carlisle Review at Carlisle 2006a, and the Tricco Review at Tricco 2015a and Tricco 2015b.

The previous Cochrane Review on drugs for prevention of PONV by Carlisle and Stevenson included RCTs investigating any drug for prevention of PONV in participants of any age undergoing general anaesthesia, regional anaesthesia, or sedation (Carlisle 2006a). This review searched several databases and included 737 studies involving 103,237 participants. Data were analysed using pair-wise meta-analyses for PONV-related outcomes and side effects comparing a drug with placebo or with another drug. Risk of bias in studies was assessed. However, the certainty of evidence was not evaluated. This review found eight drugs that effectively prevent postoperative nausea and vomiting compared to placebo: droperidol, metoclopramide, ondansetron, tropisetron, dolasetron, dexamethasone, cyclizine, and granisetron. The risk ratio (RR) versus placebo varied between 0.60 and 0.80, depending upon the drug and the outcome. This review concluded that publication bias made the evidence for differences among these drugs unreliable. Evidence for side effects was sparse: droperidol was a sedative (RR 1.32), and headache was more common after ondansetron (RR 1.16). The Carlisle Review on PONV was withdrawn in 2017, in part because this review included several studies that were retracted since publication (Carlisle 2017). Our review on prevention of PONV can be considered, to some extent, as an update to the Carlisle Review. However, to enhance the feasibility and conclusiveness of our review, we narrowed down the inclusion criteria when compared to the Carlisle review and included only adult participants undergoing general anaesthesia who received an antiemetic intervention belonging to one of the six relevant pharmacological substance classes for prevention of PONV. This enabled us to focus the research question and to limit the number of eligible RCTs. In addition, we used NMA to compare all available drugs and combinations against each other, thereby enabling us to generate a ranking of treatment efficacy. Our review included some newer drugs compared to the Carlisle Review, which are drugs of the NK_1 receptor antagonist class (aprepitant, casopitant, fosaprepitant, and rolapitant), and some of the D_2 receptor antagonists (amisulpride and haloperidol). The current review selected the best drugs based on both an important benefit for prevention of vomiting and moderate to high certainty evidence. In contrast, the Carlisle Review selected drugs that had an effect (95% CI < 1) on all four efficacy outcomes (vomiting, nausea, nausea or vomiting, and rescue antiemetic) without knowledge of the certainty of evidence. Four of the eight drugs found to be preventive for PONV in the Carlisle Review were also effective in preventing vomiting (with moderate- to high-certainty evidence) in the current review—dexamethasone, droperidol, granisetron, and ondansetron. We found three more effective drugs with moderate- to high-certainty evidence—aprepitant, fosaprepitant, and ramosetron. However, the other four effective drugs found in the Carlisle Review were not included in our review (cyclizine), were of only low-certainty evidence (dolasetron and tropisetron), or were less effective and of very low-certainty evidence (metoclopramide). The Carlisle Review emphasized that publication bias makes evidence on these drugs unreliable, especially for droperidol, ondansetron, and granisetron. In contrast to the Carlisle Review, we excluded all fraudulent studies and used an alternative strategy to assess publication bias. In our review, we also suggested publication bias for droperidol compared to placebo for vomiting. For granisetron and ondansetron compared to placebo, although estimated NMA treatment effects seem to be overestimated, the estimates were still robust in terms of the clinical conclusion. Thus, we assume that estimated treatment effects for granisetron and ondansetron were overestimated due to publication bias; however, this does not alter the conclusion. The Carlisle Review found sparse evidence for side effects, and we thoroughly underscore this statement more than 10 years later. Evidence for side effects remains limited. We also found an increase in headache for ondansetron compared to placebo with moderate-certainty evidence. We did not, however, find a sedative effect of droperidol compared to placebo found by the Carlisle Review.

A large NMA on the comparative efficacy and safety of 5-HT_3 receptor antagonists compared to each other or placebo and/or combined with other antiemetics for patients undergoing surgical procedures was published in 2015 (Tricco 2015a; Tricco 2015b). Tricco´s review had broader inclusion criteria than our review in terms of the population of interest and the study design. The Tricco Review included RCTs and non-randomized trials investigating participants of any age undergoing any surgery with any type of anaesthesia. However, the interventions of interest were focused on 5-HT_3 receptor antagonists as single interventions and in combination with other antiemetics. Tricco and colleagues searched several databases and included 450 studies with 80,410 participants for efficacy analyses (Tricco 2015a), along with 120 studies with 27,787 participants for safety analyses (Tricco 2015b). The Tricco Review was restricted to trials published in English. Risk of bias was assessed, but certainty of evidence was not evaluated. Significantly fewer patients experienced vomiting with any investigated drug relative to placebo, except for palonosetron plus dexamethasone. Tricco and associates concluded that granisetron plus dexamethasone was the most effective antiemetic. In contrast, our review included many more combinations of 5-HT_3 receptor antagonists with other antiemetics for the outcome of vomiting that were not included in the Tricco Review (aprepitant-palonosetron, aprepitant-ramosetron, CP122,721-ondansetron, aprepitant-ondansetron, casopitant-ondansetron, dexamethasone-ramosetron, haloperidol-ondansetron, ondansetron-promethazine, dexamethasone-tropisetron, droperidol-tropisetron, droperidol-palonosetron, and ondansetron-scopolamine). Estimated NMA treatment effects of single 5-HT_3 receptor antagonists compared to placebo from the Tricco Review were in agreement with our estimates of effects when transformed into odds ratios. However, the negative effect

of the combination treatment dexamethasone-palonosetron was not detected in our review. Tricco and coworkers investigated arrhythmia, QT prolongation, delirium, and mortality as relevant safety outcomes; headache and constipation as specific side effects of 5-HT_3 receptor antagonists were not included in the Tricco Review. In contrast to our review, trials with zero events in all study arms were excluded from analysis. In the Tricco Review, granisetron plus dexamethasone increased the risk of arrhythmia. This combination, however, was not included in our review, as the two relevant studies investigating this combination were not eligible for our review (El-Deeb 2011: spinal anaesthesia; Riad 2009: children). For QT prolongation, Tricco and colleagues found only two relevant trials with events investigating ondansetron versus placebo and granisetron versus placebo. Tricco and associates found three additional trials with zero events in all arms. As a limitation of the Tricco Review, the review author did not grade the certainty of evidence for the main drugs compared to placebo.

AUTHORS' CONCLUSIONS

Implications for practice

- We found high-certainty evidence showing that compared to placebo, five single drugs (aprepitant, ramosetron, granisetron, dexamethasone, and ondansetron) reduce vomiting, and moderate-certainty evidence indicating that another two single drugs (fosaprepitant and droperidol) probably reduce vomiting. These were the seven most reliable and most effective drugs identified in this review. Therefore, four of the six substance classes (5-HT_3 receptor antagonists, D_2-receptor antagonists, NK_1-receptor antagonists, and corticosteroids) with different mechanisms of action are represented by at least one drug that shows benefit in terms of preventing vomiting.
- In absolute numbers, for every 1000 patients, of whom 300 would vomit after surgery if given placebo, 282 would benefit from fosaprepitant (the most effective drug of the seven most reliable single drugs) and 18 would not. If droperidol were given (the least effective drug of the seven most reliable single drugs), 117 patients would benefit and 183 would not. Aprepitant, ramosetron, granisetron, dexamethasone, and ondansetron were ranked between fosaprepitant and droperidol in terms of their efficacy for prevention of vomiting.
- Recommended and high doses of granisetron, dexamethasone, ondansetron, and droperidol were similarly effective but were more effective than low doses for prevention of vomiting. So far, no dose effects are detectable for aprepitant, ramosetron, and fosaprepitant.
- Ranking of treatments shows that combinations of drugs were generally more effective than the corresponding single drugs in preventing vomiting. However, NK_1 receptor antagonists were the most effective drug class, and single NK_1 receptor antagonists (fosaprepitant, casopitant, aprepitant) were as effective as most of the drug combinations.
- Other single drugs of direct interest for prevention of postoperative vomiting were of uncertain effect due to very low- to low-certainty evidence (casopitant, tropisetron, dolasetron), were less effective (amisulpride, promethazine), or both (palonosetron, haloperidol, metoclopramide, rolapitant, dimenhydrinate, scopolamine), compared to placebo.
- For most of the single drugs of direct interest, we found only very low- to low-certainty evidence for safety assessed by the occurrence of SAEs and any AE. We found only moderate-certainty evidence for granisetron and amisulpride indicating that the drugs probably have little or no effect on any AE compared to placebo, and low-certainty evidence suggesting that dimenhydrinate and scopolamine may increase the number of patients with any AE.
- The certainty of evidence for most of the single drugs of direct interest ranged between very low and low for drug class-specific side effects (headache, constipation, wound infection, extrapyramidal symptoms, sedation, arrhythmia, QT prolongation, visual disturbances). An exception was moderate-certainty evidence showing that ondansetron probably increases headache and probably reduces sedation compared to placebo. The latter effect was limited to recommended and high doses of ondansetron. Droperidol probably reduces headache compared to placebo. Dexamethasone has no effect on sedation compared to placebo. Dimenhydrinate probably increases sedation and scopolamine may increase the risk for visual disturbances, both compared to placebo. No studies considered substance class-specific side effects for fosaprepitant, the most effective drug for prevention of vomiting.
- Results of the review have limited external validity for the broad population of adults undergoing any surgery with general anaesthesia, but they are directly applicable to patients at risk for PONV (i.e. women undergoing gynaecological/gastrointestinal surgery with volatile anaesthesia and patients using perioperative opioids).

Implications for research

We no longer need these types of studies.

- Aprepitant, ramosetron, granisetron, dexamethasone, ondansetron, and droperidol compared with placebo and with different other active comparators in several studies included in the NMA for vomiting. We do not need further RCTs investigating inactive or active comparisons of these six drugs in the investigated population.
- Currently, we have no need for further RCTs comparing other single drugs versus placebo for prevention of postoperative vomiting in the investigated population. Head-to-head comparisons should be the way forward for new drugs.

Here we describe future research needs.

- Fosaprepitant was compared only to ondansetron for prevention of vomiting in three studies. There is limited connectivity within the network of vomiting. Fosaprepitant should be compared to other active drugs such as granisetron, ramosetron, dexamethasone, or aprepitant to further investigate its leading position as the most effective single drug for prevention of vomiting as reported in this review. In addition, no dose-response studies nor safety studies are available for fosaprepitant in this context.
- Data on the NK_1 receptor antagonists casopitant and rolapitant are limited, although this substance class shows promising anti-vomiting effects.
- The conclusions of this review are restricted to patients at risk (women, patients undergoing gynaecological/gastrointestinal surgery, patients given inhalational anaesthesia, and patients using perioperative opioids), most of whom are healthy patients

(American Society of Anesthesiologists status (ASA) I and II) investigated in inpatient settings. To what extent patients with more severe disease or patients in outpatient settings derive benefit or harm from antiemetic prophylaxis is still unclear.

- Most patients in the general surgical population exposed to prophylactic antiemetics will not benefit because about 70% would not suffer from vomiting. Therefore, we need to understand the risk of side effects. To increase the chances of detecting even rare side effects (e.g. QT prolongation, arrhythmia, extrapyramidal symptoms), non-randomized cohort studies or systematic reviews including non-randomized studies would be useful, in addition to RCTs.
- We do not understand whether higher doses of drugs increase the chances of suffering from certain side effects. Dose-response studies on side effects or observational studies on dose effects would be useful in this regard.
- Future studies should report exact outcome definitions (e.g. QT prolongation, arrhythmia, extrapyramidal symptoms) and should fully report all investigated safety outcomes. Study authors should use online repositories and supplementary material to store detailed information.
- All new studies should prospectively publish a study protocol in an official trial registry. All outcomes of interest including outcome definition, method to measure, and time points should be listed.
- New studies should provide a detailed description of baseline characteristics and the distribution of classical risk factors for PONV in the study population (e.g. in a supplementary table).
- New RCTs should use and clearly describe methods for allocation concealment.
- All studies should declare their funding resources and potential conflicts of interest.
- Negative and non-significant results are also important. We call on all investigators who conducted studies on PONV in the past to please publish their studies, even if time has passed since the study was conducted. Only in this way can we obtain an unbiased picture of the benefits and harms of all relevant drugs.

ACKNOWLEDGEMENTS

We would like to thank Anna Lee (Content Editor); Olivia Wu and Neil Hawkins (NIHR Complex Reviews Support Unit); Kyle Kirkham, Pierre Disemunsch, and Sina Grape (Peer Reviewers); Janet Wale (Consumer Referee); Sharon Lewis (Network Support Fellow); Liz Bickerdike (Network Associate Editor); Janne Vendt (Information Specialist); Teo Quay (Managing Editor); and Andrew Smith (Co-ordinating Editor) for their help and editorial advice during preparation of this systematic review.

We would like to thank Elisabeth Friedrich-Würstlein (University Library, Würzburg) for searching and organizing full texts of articles.

We would like to thank Yvonne Jelting for her support during screening and data extraction and for sending requests to study authors for additional information.

We would like to thank Freddy Shami and Aiste Aleksaite for support provided during literature screening, translation of non-English articles, and data extraction.

We would like to thank the following people for translation of non-English articles: Woocheol Sim (Korean), Emine Yesil (Turkish), Hong Sun (Chinese), Jiechu Chen (Chinese), Shasha Chen (Chinese), Alice Mannocci (Italian), Arash Afshari (Persian, Danish), Amir Farahani (Persian), Simone Schneider (Japanese), Kota Amamoto (Japanese), Ottar Gadeholt (Danish), Alena Rudenko (Russian), Kiril Penov (Bulgarian), Argyro Fassoulaki (Greek), Oleksii Ukrainskyi (Ukranian), Arnold Weibel (Hungarian), Yvonne Jelting (Dutch), Jan Schreiber (Dutch), and Michal Chmiel (Polish).

We would like to thank Eva Kranke and Ines Guzman for secretarial support.

We received a one-time independent research grant for this review from B. BRAUN-STIFTUNG, Melsungen.

CHARACTERISTICS OF STUDIES

Characteristics of included studies *[ordered by study ID]*

Aasboe 1998

Study characteristics	
Methods	**Study design:** randomized controlled trial **Study grouping:** 2 groups, monoprophylaxis
Participants	**Baseline characteristics** Placebo • *Assessed for eligibility (n):* - • *Enrolled (n):* - • *Randomized (n):* 40 • *Received treatment (n):* NA • *Analysed (n):* 40 • *Age (mean ± SD, median (IQR), median (range)):* 45 ± 14 • *Weight (mean ± SD, median (IQR), median (range)):* 64 ± 11 • *BMI (mean ± SD, median (IQR), median (range)):* NA • *ASA I/II/III/IV (n):* NA/NA/NA/0 • *Gender (female in %):* 87.5 • *Non-smoker (%):* NA • *History of PONV/motion sickness (%):* NA • *Type of general anaesthesia: inhalational anaesthesia (isoflurane, N_2O)* • *Duration of anaesthesia or surgery (in min; as mean or median):* 16 (haemorrhoids), 25 (hallux valgus) • *Use of perioperative opioids (if yes, which?):* fentanyl at induction (2 µg/kg), meperidine (10 mg IV) or codeine (30 mg) as rescue analgesic (NA) • *Type of surgery:* haemorrhoids, hallux valgus Betamethasone • *Assessed for eligibility (n):* - • *Enrolled (n):* - • *Randomized (n):* NA • *Received treatment (n):* NA • *Analysed (n):* 38 • *Age (mean ± SD, median (IQR), median (range)):* 44 ± 13 • *Weight (mean ± SD, median (IQR), median (range)):* 65 ± 10 • *BMI (mean ± SD, median (IQR), median (range)):* NA • *ASA I/II/III/IV (n):* NA/NA/NA/0 • *Gender (female in %):* 73.68 • *Non-smoker (%):* NA • *History of PONV/motion sickness (%):* NA • *Type of general anaesthesia: inhalational anaesthesia (isoflurane, N_2O)* • *Duration of anaesthesia or surgery (in min; as mean or median):* 15 (haemorrhoids), 26 (hallux valgus) • *Use of perioperative opioids (if yes, which?):* fentanyl at induction (2 µg/kg), meperidine (10 mg IV) or codeine (30 mg) as rescue analgesic (NA) • *Type of surgery:* haemorrhoids, hallux valgus **Included criteria:** age over 18 years, ASA I to III, no corticosteroids during last week or NSAIDs during the 2 days before operation, scheduled for ambulatory surgery (hallux valgus (Mitchell's operation) or haemorrhoids (Milligan's operation))

Aasboe 1998 *(Continued)*

	Excluded criteria: known allergy or contraindications to any of the test drugs, pregnancy **Pretreatment:** baseline characteristics (age, weight): no; (ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia): no; (history of PONV/motion sickness, non-smoker, perioperative opioids): unclear
Interventions	**Intervention characteristics** Placebo • *Dose*: saline 2 mL • *Time point of administration*: 30 minutes before the start of surgery • *Route of administration*: IM • *Rescue antiemetics (if yes, which?)*: metoclopramide 10 mg IV Betamethasone • *Dose*: 12 mg (50% betamethasone disodium phosphate and 50% betamethasone acetate) • *Time point of administration*: 30 minutes before the start of surgery • *Route of administration*: IM • *Rescue antiemetics (if yes, which?)*: metoclopramide 10 mg IV
Outcomes	*Adverse events (general notes in the publication, 4 hours' observation)* • Outcome type: general note on side effects
Identification	**Sponsorship source:** financial support was provided as a research grant before study start from Schering-Plough, Norway, the distributor of Celeston Chronodose (betamethasone) **Country:** Norway **Setting:** outpatient, single-centre **Author's name:** Vidar Aasboe **Institution:** Departments of Anesthesia and Surgery, Ullevaal University Hospital, Oslo, Norway **Email:** NA **Address:** Department of Anesthesia, Oestfold Central Hospital, N-1603 Fredrikstad, Norway **Duration of study:** NA **Language:** English **Study's primary outcome:** postoperative pain **Trial registry number:** NA
Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "the patients were randomly assigned to double-blind administration from coded ampoules of 2 mL of the test drug IM 30 min before the start of surgery" Judgement comment: no further information on sequence generation provided

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Aasboe 1998 *(Continued)*

Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding ("double-blind")
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Quote: "the day after surgery, the patients were contacted by telephone and asked to evaluate their pain using the verbal score during rest, ambulation, sitting in a chair (for hemorrhoid patients), and leg movement (for hallux valgus patients). They were also asked about analgesic consumption and the occurrence of PONV. The patients were asked to evaluate their overall experience during the postoperative period as unacceptable, adequate, or good. A similar telephone interview was performed 7 days after the surgery" Judgement comment: insufficient information on blinding ("double-blind")
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "eighty patients were included in the study. Two patients were excluded because the surgical procedure was changed after inclusion"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "there were no significant differences between the two groups in demographic data (Table 1) or vital signs in the perioperative period" Judgement comment: baseline characteristics (age, weight): no; (ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia): no; (history of PONV/motion sickness, non-smoker, perioperative opioids): unclear

Abreu 2006

Study characteristics	
Methods	**Study design:** randomized controlled trial **Study grouping:** 5 groups, monoprophylaxis
Participants	**Baseline characteristics** Ondansetron • *Assessed for eligibility (n)*: - • *Enrolled (n)*: - • *Randomized (n)*: 20 • *Received treatment (n)*: NA • *Analysed (n)*: 20 (not explicitly stated) • *Age (mean ± SD, median (IQR), median (range))*: 34.53 ± 5.50 • *Weight (mean ± SD, median (IQR), median (range))*: 60.58 ± 10.12 • *BMI (mean ± SD, median (IQR), median (range))*: NA • *ASA I/II/III/IV (n)*: 14/6/0/0 • *Gender (female in %)*: 100 • *Non-smoker (%)*: NA • *History of PONV/motion sickness (%)*: 0/NA

Abreu 2006 *(Continued)*

- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 103.33
- *Use of perioperative opioids (if yes, which?)*: 175 mg fentanyl
- *Type of surgery*: gynaecological laparoscopy

Metoclopramide

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 20
- *Received treatment (n)*: NA
- *Analysed (n)*: 20 (not explicitly stated)
- *Age (mean ± SD, median (IQR), median (range))*: 34.30 ± 7.78
- *Weight (mean ± SD, median (IQR), median (range))*: 64.43 ± 13.15
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 16/4/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 0/NA
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 80.53
- *Use of perioperative opioids (if yes, which?)*: 175 mg fentanyl
- *Type of surgery*: gynaecological laparoscopy

Droperidol

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 20
- *Received treatment (n)*: NA
- *Analysed (n)*: 20 (not explicitly stated)
- *Age (mean ± SD, median (IQR), median (range))*: 34.23 ± 9.24
- *Weight (mean ± SD, median (IQR), median (range))*: 62.82 ± 10.04
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 16/4/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 0/NA
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 93.42
- *Use of perioperative opioids (if yes, which?)*: 190.52 mg fentanyl
- *Type of surgery*: gynaecological laparoscopy

Dexamethasone

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 20
- *Received treatment (n)*: NA
- *Analysed (n)*: 20 (not explicitly stated)
- *Age (mean ± SD, median (IQR), median (range))*: 31.56 ± 5.58
- *Weight (mean ± SD, median (IQR), median (range))*: 59.43 ± 12.75
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 17/3/0/0

Abreu 2006 *(Continued)*

- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 0/NA
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 89.74
- *Use of perioperative opioids (if yes, which?)*: 188.16 mg fentanyl
- *Type of surgery*: gynaecological laparoscopy

Control

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 20
- *Received treatment (n)*: NA
- *Analysed (n)*: 20 (not explicitly stated)
- *Age (mean ± SD, median (IQR), median (range))*: 35.60 ± 6.26
- *Weight (mean ± SD, median (IQR), median (range))*: 57.52 ± 9.58
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 16/4/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 0/NA
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 100.37
- *Use of perioperative opioids (if yes, which?)*: 180.78 mg fentanyl
- *Type of surgery*: gynaecological laparoscopy

Included criteria: patients aged 22 to 62 years, physical status ASA I and II, submitted to diagnostic or surgical gynaecological laparoscopy under general intravenous and inhalational anaesthesia

Excluded criteria: patients with previous history of postoperative nausea and vomiting, those with gastric disorders

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, history of PONV, perioperative opioids): no; (non-smoker, history of motion sickness): unclear; (duration of anaesthesia): yes

Interventions	**Intervention characteristics** Ondansetron • *Dose*: 4 mg • *Time point of administration*: after anaesthetic induction • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: NA Metoclopramide • *Dose*: 10 mg • *Time point of administration*: after anaesthetic induction • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: NA Droperidol • *Dose*: 1.25 mg • *Time point of administration*: after anaesthetic induction • *Route of administration*: IV

Abreu 2006 *(Continued)*

	• *Rescue antiemetics (if yes, which?)*: NA Dexamethasone • *Dose*: 8 mg • *Time point of administration*: after anaesthetic induction • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: NA Control • *Dose*: no treatment • *Time point of administration*: no treatment • *Route of administration*: no treatment • *Rescue antiemetics (if yes, which?)*: NA
Outcomes	*Vomiting* (PACU or PACU + 4 hours (discharge)) • Outcome type: dichotomous outcome
Identification	**Sponsorship source:** NA **Country:** Brazil **Setting:** outpatient, single-centre **Author's name:** Múcio Paranhos de Abreu **Institution:** Hospital Centro Médico de Campinas e Instituto Penido Burnier, Campinas, SP **Email:** mpabreu2@gmail.com **Address:** Av. Nossa Senhora de Fátima, 805/J-131 Taquaral13090-000 Campinas, SP **Language:** English/Portuguese **Duration of study:** NA **Trial registry number:** NA **Study's primary outcome:** NA
Notes	Data on incidence of vomiting not plausible when 20 participants per group assumed

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "patients were randomly distributed in five groups according to the antiemetic drug, administered immediately after anesthetic induction: group GO: ondansetron (4 mg); group GM: metoclopramide (10 mg); group GD: droperidol (1.25 mg); group GX: dexamethasone (8 mg) and group GC (control) not medicated" Judgement comment: no information on randomization method provided
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias)	Unclear risk	Judgement comment: no statement

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Abreu 2006 *(Continued)*

All outcomes		
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Quote: "during PACU stay, the presence of nausea and/or vomiting was periodically evaluated and recorded by an anaesthesiologist" Judgement comment: no statement on blinding
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: missing information on number of analysed participants in different groups (incidence of vomiting). Table 1 (demographic data) for all participants We assumed no missing outcome data for incidence of vomiting
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, history of PONV, perioperative opioids): no; (non-smoker, history of motion sickness): unclear; (duration of anaesthesia): yes

Included criteria: 18 to 75 years of age, ASA physical status I and II, undergoing general anaesthesia for laparoscopic cholecystectomy

Excluded criteria: history of gastrointestinal or neuromuscular disease, known narcotic use or alcohol abuse, patients under 18 or over 75 years of age, patients with nausea and vomiting within 72 hours of surgery or who had received antiemetic therapy

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, perioperative opioids): no; (history of PONV/motion sickness, non-smoker): unclear

Interventions

Intervention characteristics

Ondansetron

- *Dose*: 8 mg
- *Time point of administration*: 2 minutes before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: NA

Metoclopramide

- *Dose*: 10 mg
- *Time point of administration*: 2 minutes before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: NA

Ondansetron + dexamethasone

- *Dose*: ondansetron 8 mg, dexamethasone 8 mg
- *Time point of administration*: 2 minutes before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: NA

Metoclopramide + dexamethasone

- *Dose*: metoclopramide 10 mg, dexamethasone 8 mg
- *Time point of administration*: 2 minutes before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: NA

Placebo

- *Dose*: saline
- *Time point of administration*: 2 minutes before induction of anaesthesia

- *Type of general anaesthesia*: balanced anaesthesia (isoflurane, morphine)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 259.1
- *Use of perioperative opioids (if yes, which?)*: intraoperative fentanyl (4 µg/kg at induction, 2 µg/kg/h during CPB), intraoperative morphine (0.1 mg/kg), postoperative morphine (9.5 mg)
- *Type of surgery*: cardiac surgery with cardiopulmonary bypass

Included criteria: consecutive patients undergoing elective cardiac surgery with cardiopulmonary bypass: underwent coronary artery bypass grafting, valve-related and combined procedures; adult patients between 18 and 70 years of age with American Society of Anesthesiologists (ASA) physical status of II or III

Excluded criteria: past history of hiatus hernia, heartburn, or previous gastric surgery; those with morbid obesity, mental retardation, or psychiatric illness; patients taking antiemetic medication, H2-receptor antagonist, or proton pump inhibitor; not tracheally extubated within 12 hours after end of surgery; intra-aortic balloon pump (IABP) requirement during surgery, emergency resternotomy

Notes	3 out of 4 groups relevant

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "based on a computer-generated randomization table 20"
Allocation concealment (selection bias)	Unclear risk	Quote: "the participants were allocated by the anesthesiologist to one of the four groups of antiemetic prophylaxis" Judgement comment: no statement on allocation concealment
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote: "study drug was prepared and administered by an anesthesiologist at the investigative site who was not involved in data collection" Judgement comment: anaesthetists not blinded. No information on blinding of participants
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "the incidence and severity of nausea and vomiting were recorded by a blinded investigator, who was not involved in anesthetic and ICU care"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "128 met inclusion criteria, provided informed consent, and were qualified for the study. Eight patients were excluded from the data; two because of protocol violation, three for prolonged ventilation after the end of surgery, one required intraoperative IABP and two required resternotomy for bleeding. Finally, 120 patients were eligible for the statistical analysis"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "patients' characteristics, including demographic data and baseline characteristics are described in table 1. There were no significant differences among the four groups in factors that could modify the incidence of PONV as background factors, factors related to the operation or anesthesia. Average risk of PONV, according to simplified risk score by Apfel and colleagues, 23 was not statistically different among the four groups. There were no significant differences in pain intensity and total dose of postoperative opioids among groups in the ICU" Judgement comment: baseline characteristics (age, BMI, ASA): no difference. Potential effect modifiers (gender, non-smoker, history of PONV, anaesthesia, use of perioperative opioids): no difference; (history of motion sickness, use of intraoperative opioids): unclear

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "patients were allocated randomly, using a closed envelope technique, in blocks of 50 to three groups in a 2:2:1 ratio"
Allocation concealment (selection bias)	Unclear risk	Quote: "using a closed envelope technique" Judgement comment: not stated: "sequentially numbered and opaque" envelopes
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Quote: "each treatment was given as two 10 ml i.v. injections. These were prepared by a single investigator who took no part in data collection" Judgement comment: insufficient information on blinding of anaesthetists
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "all data were recorded by a single research nurse who remained blinded to the treatment groups throughout the study"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "one patient who underwent laparotomy (control group) was withdrawn from the study. Data before discharge from 139 patients were analysed"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "all groups were comparable for patient characteristics, pain and analgesic requirement. No patient required the administration of atropine or glycopyrrolate for intra-operative bradycardia" Judgement comment: baseline characteristics (age, BMI): no; (ASA): unclear. Potential effect modifiers (gender, history of PONV/motion sickness, perioperative opioids): no; (duration of anaesthesia, non-smoker): unclear

Pretreatment: baseline characteristics (age, weight): no; (ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness, perioperative opioids): no; (non-smoker): unclear

---

Interventions

Intervention characteristics

Tropisetron (group T)

- *Dose*: 5 mg
- *Time point of administration*: immediately after anaesthesia induction
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: metoclopramide 10 mg IV; 22.8%

Placebo (group P)

- *Dose*: saline
- *Time point of administration*: immediately after anaesthesia induction
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: metoclopramide 10 mg IV; 71.4%

Outcomes

Vomiting or retching (0 to 24 hours)

- Outcome type: dichotomous outcome

Nausea (0 to 24 hours)

- Outcome type: dichotomous outcome

Complete response (no PONV) in 24 hours

- *Use of perioperative opioids (if yes, which?)*: 1.5 mg/kg tramadol at induction
- *Type of surgery*: laparoscopic cholecystectomy

Placebo (group P)

- *Assessed for eligibility (n)*: .
- *Enrolled (n)*: -
- *Randomized (n)*: NA
- *Received treatment (n)*: NA
- *Analysed (n)*: 60
- *Age (mean ± SD, median (IQR), median (range))*: 44.0 ± 14.9
- *Weight (mean ± SD, median (IQR), median (range))*: 76 ± 15.7
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA/NA/0/0
- *Gender (female in %)*: 88.33
- *Non-smoker (%)*: 96.67
- *History of PONV/motion sickness (%)*: 5/0
- *Type of general anaesthesia*: TIVA (propofol)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 60.3
- *Use of perioperative opioids (if yes, which?)*: 1.5 mg/kg tramadol at induction
- *Type of surgery*: laparoscopic cholecystectomy

Included criteria: ASA I and II, 18 to 70 years of age, scheduled for elective laparoscopic cholecystectomy under general anaesthesia

Excluded criteria: had received antiemetics or cortisone within 48 hours before surgery; required opioids before and after surgery; pregnant or breastfeeding; BMI > 34 kg/m^2; gastrointestinal, hepatic, renal, mental, or psychiatric illness; history of motion sickness; if postoperatively, VAS persisted at > 4; subsequent 2 mg dose of morphine given

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Interventions

Intervention characteristics

Ondansetron (group O)

- *Dose*: 4 mg
- *Time point of administration*: immediately after induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 7% (metoclopramide 10 mg)

Dexamethasone (group D)

- *Dose*: 8 mg
- *Time point of administration*: immediately after induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 8% (metoclopramide 10 mg)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "table of randomized numbers" Quote: "patients were randomly assigned to one of three groups"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "a table of randomized numbers. The anesthetists, surgeons, and nurses managing these patients were blinded to the study drugs. The same anesthetics and techniques"
Blinding of outcome assessment (detection bias)	Low risk	Quote: "the postoperative data collection was performed by an anesthesia resident blinded to the study groups"

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Alghanem 2010 *(Continued)*

All outcomes		
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "of the 196 patients who consented to participate in the study, 180 (60 in each group; 147 females and 33 males) completed the study, and 16 who received morphine for postoperative analgesia were excluded. Data from the 180 study patients were analyzed"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: NCT00825071 (retrospective registration)
Other bias	Low risk	Quote: "there were no significant statistical differences in demographic data among the groups (Table 1). The patient-related risk factors, Apfel score, and surgically related risk factors (duration of surgery and gas insufflation) for PONV were similar between the groups (Table 1)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "the study, the patients were randomised according to a randomisation list, generated by the pharmacy. Block randomization was used for nine patients in each group. Twelve patients were lost to..."
Allocation concealment (selection bias)	Low risk	Judgement comment: central allocation Replacement of 12 participants who were lost to follow-up by sealed envelopes (minority of study population; 2%)
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote: "the two groups treated with antiemetic were blinded to all involved in administration and anaesthesia. The control group was not blinded to the anaesthetist but to all other personnel" Judgement comment: high risk of bias for the 2 groups treated with antiemetics vs control Low risk of bias for the droperidol vs granisetron
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "during analysis the treatment groups were concealed and only the labels provided by the pharmacy identified which group the patient belonged to" Quote: "the two groups treated with antiemetic were blinded to all involved in administration and anaesthesia. The control group was not blinded to the anaesthetist but to all other personnel"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "out of the 495 patients were lost to follow-up. Another 12 patients were added at the end of the study. Response rate was 98%"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Judgement comment: baseline characteristics (age, BMI): no; (ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

- *Analysed (n)*: 40
- *Age (mean ± SD, median (IQR), median (range))*: 36 (20 to 62)
- *Weight (mean ± SD, median (IQR), median (range))*: 63 (42 to 120)
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA/NA/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 20/NA
- *Type of general anaesthesia*: inhalational anaesthesia (enflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 45
- *Use of perioperative opioids (if yes, which?)*: intraoperative fentanyl (18 patients), nicomorphine sc as rescue analgesic (NA)
- *Type of surgery*: gynaecological surgery

Included criteria: ASA I and II, 17 to 72 years of age, scheduled to undergo general anaesthesia for gynaecological surgery

Excluded criteria: clinical or laboratory evidence of severe renal, haematologic, or hepatic abnormalities, metabolic disorders accompanied by increased incidence of nausea and vomiting such as diabetes mellitus; history of drug abuse; previous allergic reactions to serotonin antagonists; any antiemetic therapy within 24 hours before surgery

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV): no; (history of motion sickness, non-smoker, perioperative opioids): unclear

Interventions	**Intervention characteristics** Tropisetron • *Dose*: 5 mg • *Time point of administration*: 10 minutes before induction of anaesthesia • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 10% (Itinerol B6, containing a combination of 50 mg meclozine, 50 mg piridoxine, 20 mg caffeine) Placebo • *Dose*: matching placebo • *Time point of administration*: 10 minutes before induction of anaesthesia • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 20% (Itinerol B6, containing a combination of 50 mg meclozine, 50 mg piridoxine, 20 mg caffeine)
Outcomes	*Vomiting (0 to 24 hours)* • Outcome type: dichotomous outcome *Vomiting (0 to 4 hours)* • Outcome type: dichotomous outcome *Vomiting (4 to 24 hours)* • Outcome type: dichotomous outcome *Nausea (0 to 24 hours)* • Outcome type: dichotomous outcome

Participants

Baseline characteristics

Ondansetron (cohort A)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 242
- *Received treatment (n)*: NA
- *Analysed (n)*: 229
- *Age (mean ± SD, median (IQR), median (range))*: 44.8 ± 12.44
- *Weight (mean ± SD, median (IQR), median (range))*: 70.6 ± 17.05
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 94/145/2/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: 100
- *History of PONV/motion sickness (%)*: 100
- *Type of general anaesthesia*: balanced general anaesthesia
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 92.1
- *Use of perioperative opioids (if yes, which?)*: yes
- *Type of surgery*: hysterectomy, cholecystectomy, breast operation, thyroid operation, bilateral salpingo-oophorectomy

Ondansetron + casopitant (cohort B)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 242
- *Received treatment (n)*: NA
- *Analysed (n)*: 227
- *Age (mean ± SD, median (IQR), median (range))*: 44.4 ± 12.19
- *Weight (mean ± SD, median (IQR), median (range))*: 72.3 ± 17.55
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 87/152/1/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: 100
- *History of PONV/motion sickness (%)*: 100
- *Type of general anaesthesia*: balanced general anaesthesia
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 87.7
- *Use of perioperative opioids (if yes, which?)*: yes
- *Type of surgery*: hysterectomy, cholecystectomy, breast operation, thyroid operation, bilateral salpingo-oophorectomy

Included criteria: 18 years of age or older; ASA I and II; 4 Apfel risk factors for PONV (female sex, history of PONV and/or motion sickness, non-smoker status, and anticipated to receive opioids postoperatively); scheduled to undergo one of the following surgical procedures: breast surgery, orthopaedic shoulder surgery, or thyroid surgery; laparoscopic or laparotomy procedures for cholecystectomy, hysterectomy, or other gynaecological surgery; anticipated to involve general anaesthesia of at least 1 hour; anaesthetic regimens not specified but investigators required to adhere to a balanced general anaesthetic regimen (propofol was permitted for induction of anaesthesia, TIVA was not allowed in this study)

Excluded criteria: anticipated to require a nasogastric or oral gastric tube with intermittent or continuous suctioning postoperatively; had received medication with potential antiemetic activity in the 24-

Duration of study: 20 March to 31 August 2006

Language: English

Study's primary outcome: proportion of patients who achieved a complete response, defined as no vomiting, retching, or rescue therapy

Trial registry number: NCT00326248, EUCTR2005-005856-42

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "patients were randomized to 1 of 2 treatment arms" Judgement comment: no further information on sequence generation provided
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding ("double-blind")
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding ("double-blind")
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "in total, 456 patients (94.2%) completed the study: 229 (94.6%) in cohort A and 227 (93.8%) in cohort B. The reasons for the premature withdrawal of the 28 patients were as follows: 7 were lost to follow-up (3 [1.3%] in cohort A and 4 [1.8%] in cohort B), 3 had protocol violations (2 [0.9%] in cohort A and 1 [0.4%] in cohort B), 5 decided to withdraw (1 [0.4%] in cohort A and 4 [1.8%] in cohort B), and 13 withdrew because of other reasons (7 [3.1%] in cohort A and 6 [2.6%] in cohort B), including cancelled surgery (4 in cohort A and 3 in cohort B), closed to recruitment (1 in each group), and treatment failure (1 in cohort A)"
Selective reporting (reporting bias)	Low risk	Judgement comment: NCT00326248 (retrospective registration), EUCTR2005-005856-42 (prospective registration). The prospectively registered primary outcome (complete response) was reported in the prespecified way in the final study report
Other bias	Low risk	Quote: "demographic characteristics were well balanced among the treatment groups" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

- *Analysed (n)*: 65
- *Age (mean ± SD, median (IQR), median (range))*: 39.63 ± 4.74 (32 to 43)
- *Weight (mean ± SD, median (IQR), median (range))*: 53.1 ± 2.7 (51 to 60)
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA/NA/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: NA/0
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 68.8
- *Use of perioperative opioids (if yes, which?)*: fentanyl for induction, postoperative tramadol
- *Type of surgery*: laparoscopic cholecystectomy

Included criteria: women between 30 and 50 years of age (ASA I and II) undergoing elective standard 4-port laparoscopic cholecystectomy at J.N. Medical College Hospital, A.M.U., Aligarh

Excluded criteria: history of motion sickness, gastrointestinal disease; receiving antiemetics within 24 hours before surgery; receiving long-term steroid therapy; diabetes mellitus or cardiovascular disease

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of motion sickness): no; (history of PONV, non-smoker, perioperative opioids): unclear

Interventions	**Intervention characteristics** Ondansetron • *Dose*: 4 mg • *Time point of administration*: before shifting of patient from operating room to postoperative unit • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 41.5 (metoclopramide 10 mg IV) Ramosetron • *Dose*: 0.3 mg • *Time point of administration*: before shifting of patient from operating room to postoperative unit • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 27.7 (metoclopramide 10 mg IV)
Outcomes	*Vomiting (0 to 24 hours)*

Study's primary outcome: complete absence of nausea and vomiting

Trial registry number: NA

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "using a computer generated table of random numbers"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "study drugs were mixed with 0.9% saline to a final volume of 5 ml by personnel not involved in the study and were administered in a double-blind fashion"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "in the postanaesthesia care unit, patients were observed by the same nurse who was blinded to study group assignment"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "of 93 patients enrolled, four were excluded (3 loss to follow-up, 1 protocol violation). Therefore, data from 89 patients were analyzed in the postanaesthesia care unit: 29 haloperidol, 30 ondansetron and 30 controls (see Fig. 1). In addition, two patients in the haloperidol group and three patients each in the ondansetron and the placebo group were lost to longterm follow-up. Thus, 27 patients in each group were analyzed for 24 h following discharge from the postanaesthesia care unit. There were no differences among"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Quote: "there were no differences among the groups with respect to patients' characteristics, type of surgery, duration of anaesthesia, emergence time, average fentanyl consumption and average Lactated Ringer received (Table 1). No difference among the groups was noted with respect to risk factors predisposing to PONV (Table 2)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of motion sickness): no; (perioperative opioids, history of PONV > 20%): yes

Included criteria: elective surgery during general anaesthesia that was expected to last at least 1 hour, risk of postoperative nausea and vomiting that exceeded 40% (presence of at least 2 of the following risk factors: female sex, non-smoker status, previous history of postoperative nausea and vomiting or motion sickness, anticipated use of postoperative opioids)

Excluded criteria: contraindication to any of the study drugs, had taken emetogenic or antiemetic drugs within the 24 hours before surgery, expected to require postoperative mechanical ventilation, pregnant or lactating

Pretreatment: baseline characteristics (age): no; (weight, BMI, ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Interventions

Intervention characteristics

Control

- *Dose*: no treatment
- *Time point of administration*: -
- *Route of administration*: -
- *Rescue antiemetics (if yes, which?)*: 4 mg ondansetron; if symptoms persisted, 4 mg of dexamethasone and 1.25 mg of droperidol were added

Droperidol

- *Dose*: 1.25 mg
- *Time point of administration*: within 20 minutes after start of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 4 mg ondansetron; if symptoms persisted, 4 mg of dexamethasone and 1.25 mg of droperidol were added

Dexamethasone

- *Dose*: 4 mg
- *Time point of administration*: within 20 minutes after start of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 4 mg ondansetron; if symptoms persisted, 4 mg of dexamethasone and 1.25 mg of droperidol were added

Ondansetron

- *Dose*: 4 mg
- *Time point of administration*: during the last 20 minutes of surgery
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 4 mg ondansetron; if symptoms persisted, 4 mg of dexamethasone and 1.25 mg of droperidol were added

Country: Germany, Finland, England, Turkey, Slovakia, Spain, UK, Austria

Setting: multi-centre (28)

Author's name: Christian C. Apfel

Institution: Julius-Maximilians Universität, Würzburg, Germany

Email: apfel@ponv.org

Address: Outcomes Research Institute, 501 East Broadway, Suite 210, Louisville, KY 40202, USA

Duration of study: 2 February 2000 to 30 July 2002

Language: English, German

Study's primary outcome: incidence of any nausea, vomiting, or both during first 24 hours after surgery.

Trial registry number: Controlled Clinical Trials 24 (2003), 736-751

Notes	Factorial trial design. Used as 2 sub-studies (propofol, inhalational anaesthesia), each with 8 groups

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "therefore, permuted blocks of 96 (2 3 ¬3¬2 2) patients were generated. Each center received four blocks with a unique computerized randomization"
Allocation concealment (selection bias)	Low risk	Quote: "stored in sequentially numbered, sealed, opaque envelopes" Quote: "the envelopes were opened after consent was obtained, just before the induction of general anesthesia"
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote: "the anesthesiologists responsible for intraoperative management were not blinded to the treatment, but they were not involved in the postoperative assessment"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "after the 2nd and 24th postoperative hours, trained investigators who were fully blinded to the intraoperative management and random treatment assignments recorded the number of emetic episodes and the time each one occurred"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "outcome data were incomplete for 38 patients, leaving 5161 patients (99 percent) for whom complete outcome data were available. One center each did not randomize with respect to carrier gas (424 patients), use of remifentanil or fentanyl (191 patients), or both of these factors (181 patients). Three centers randomly assigned a total of 280 patients to 80 percent oxygen in nitrogen (as a third alternative to 30 percent oxygen in nitrogen or in nitrous oxide). A total of 4123 patients were thus randomly assigned with respect to all six primary factors, and outcome data were incomplete in 37 of them (1 patient with incomplete data was among those not randomly assigned with respect to carrier gas), leaving 4086 patients (99 percent) for whom complete outcome data could be analyzed (Fig. 1)"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: study protocol published in Controlled Clinical Trials 24 (2003) 736-751 (retrospective registration)

- *Type of surgery*: gynaecological surgery, hysterectomy, head and neck surgery, cholecystectomy, thyroid surgery, hernia repair, breast surgery, hip replacement, arm or hand surgery, knee arthroscopy, others (overall information on type of surgery, not group specific)

Dexamethasone

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: NA
- *Received treatment (n)*: NA
- *Analysed (n)*: 340
- *Age (mean ± SD, median (IQR), median (range))*: 47
- *Weight (mean ± SD, median (IQR), median (range))*: NA
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA
- *Gender (female in %)*: 81.5
- *Non-smoker (%)*: 81.2
- *History of PONV/motion sickness (%)*: 54.5
- *Type of general anaesthesia*: TIVA
- *Duration of anaesthesia or surgery (in min; as mean or median)*: NA
- *Use of perioperative opioids (if yes, which?)*: NA
- *Type of surgery*: gynaecological surgery, hysterectomy, head and neck surgery, cholecystectomy, thyroid surgery, hernia repair, breast surgery, hip replacement, arm or hand surgery, knee arthroscopy, others (overall information on type of surgery, not group specific)

Ondansetron

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: NA
- *Received treatment (n)*: NA
- *Analysed (n)*: 338
- *Age (mean ± SD, median (IQR), median (range))*: 47
- *Weight (mean ± SD, median (IQR), median (range))*: NA
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA
- *Gender (female in %)*: 81.5
- *Non-smoker (%)*: 81.2
- *History of PONV/motion sickness (%)*: 54.5
- *Type of general anaesthesia*: TIVA
- *Duration of anaesthesia or surgery (in min; as mean or median)*: NA
- *Use of perioperative opioids (if yes, which?)*: NA
- *Type of surgery*: gynaecological surgery, hysterectomy, head and neck surgery, cholecystectomy, thyroid surgery, hernia repair, breast surgery, hip replacement, arm or hand surgery, knee arthroscopy, others (overall information on type of surgery, not group specific)

Dexamethasone + droperidol

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: NA
- *Received treatment (n)*: NA
- *Analysed (n)*: 341
- *Age (mean ± SD, median (IQR), median (range))*: 47
- *Weight (mean ± SD, median (IQR), median (range))*: NA

- *Type of surgery*: gynaecological surgery, hysterectomy, head and neck surgery, cholecystectomy, thyroid surgery, hernia repair, breast surgery, hip replacement, arm or hand surgery, knee arthroscopy, others (overall information on type of surgery, not group specific)

Included criteria: elective surgery during general anaesthesia that was expected to last at least 1 hour, risk of postoperative nausea and vomiting that exceeded 40% (presence of at least 2 of the following risk factors: female sex, non-smoker status, previous history of postoperative nausea and vomiting or motion sickness, anticipated use of postoperative opioids)

Excluded criteria: contraindication to any of the study drugs, those who had taken emetogenic or antiemetic drugs within the 24 hours before surgery, those who were expected to require postoperative mechanical ventilation, those who were pregnant or lactating

Pretreatment: baseline characteristics (age): no; (weight, BMI, ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Interventions

Intervention characteristics

Control

- *Dose*: no treatment
- *Time point of administration*: -
- *Route of administration*: -
- *Rescue antiemetics (if yes, which?)*: 4 mg ondansetron; if symptoms persisted, 4 mg of dexamethasone and 1.25 mg of droperidol were added

Droperidol

- *Dose*: 1.25 mg
- *Time point of administration*: within 20 minutes after start of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 4 mg ondansetron; if symptoms persisted, 4 mg of dexamethasone and 1.25 mg of droperidol were added

Dexamethasone

- *Dose*: 4 mg
- *Time point of administration*: within 20 minutes after start of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 4 mg ondansetron; if symptoms persisted, 4 mg of dexamethasone and 1.25 mg of droperidol were added

Setting: multi-centre (28)

Author's name: Christian C. Apfel

Institution: Julius-Maximilians Universität, Würzburg, Germany

Email: apfel@ponv.org

Address: Outcomes Research Institute, 501 East Broadway, Suite 210, Louisville, KY 40202, USA

Duration of study: 2 February 2000 to 30 July 2002

Language: English, German

Study's primary outcome: incidence of any nausea, vomiting, or both during first 24 hours after surgery

Trial registry number: Controlled Clinical Trials 24 (2003), 736-751

Notes	Factorial trial design. Used as 2 sub-studies (propofol, inhalational anaesthesia), each with 8 groups

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "therefore, permuted blocks of 96 (2 3 ¬3¬2 2) patients were generated. Each center received four blocks with a unique computerized randomization"
Allocation concealment (selection bias)	Low risk	Quote: "stored in sequentially numbered, sealed, opaque envelopes" Quote: "the envelopes were opened after consent was obtained, just before the induction of general anesthesia"
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote: "the anesthesiologists responsible for intraoperative management were not blinded to the treatment, but they were not involved in the postoperative assessment"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "after the 2nd and 24th postoperative hours, trained investigators who were fully blinded to the intraoperative management and random treatment assignments recorded the number of emetic episodes and the time each one occurred"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "outcome data were incomplete for 38 patients, leaving 5161 patients (99 percent) for whom complete outcome data were available. One center each did not randomize with respect to carrier gas (424 patients), use of remifentanil or fentanyl (191 patients), or both of these factors (181 patients). Three centers randomly assigned a total of 280 patients to 80 percent oxygen in nitrogen (as a third alternative to 30 percent oxygen in nitrogen or in nitrous oxide). A total of 4123 patients were thus randomly assigned with respect to all six primary factors, and outcome data were incomplete in 37 of them (1 pa-

Apfel 2004-2 *(Continued)*

		tient with incomplete data was among those not randomly assigned with respect to carrier gas), leaving 4086 patients (99 percent) for whom complete outcome data could be analyzed (Fig. 1)"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: study protocol published in Controlled Clinical Trials 24 (2003) 736-751 (retrospective registration)
Other bias	Unclear risk	Judgement comment: baseline characteristics (age): no; (weight, BMI, ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "based on computer generated random number list (nQuery program)"
Allocation concealment (selection bias)	Unclear risk	Quote: "the study solution was prepared by a nurse not involved in the perioperative and postoperative care of the patient three hours before surgery. Then it was given to the patient in a sealed envelope, which was handed over to the anesthesiologist who was not involved in the study" Judgement comment: not mentioned: opaque, sequentially numbered envelopes (SNOSE)
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "patients, anesthesiologists, and the follow-up team were blinded to the administered drugs"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "all patients, anesthesiologists, and the follow-up team were blinded to the administered drugs"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "fifty-two patients undergoing gynecological laparotomy surgery were recruited. Three patients were excluded due to receiving succinylcholine for induction, operative time more than three hours, and having paracoxib for pain relief in the postanesthesia care unit"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: TCTR20151116001 (retrospective registration)
Other bias	High risk	Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender): no; (history of PONV/motion sickness, non-smoker): unclear; (perioperative opioids, duration of anaesthesia -> significant P values): yes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "using a computer-generated randomized list"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the syringes containing each drug were identical and were prepared by personnel not involved in the study"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "these parameters were measured immediately after surgery (0 h), and at 3 h, 6 h, and 12 h postoperatively by anesthesia residents blinded to which antiemetic the patient had received"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "were enrolled in the study. Patients' demographics were similar in all study groups (Table 1). Both groups A" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness): no; (non-smoker, perioperative opioids): unclear

Arslan 2011

Study characteristics

Methods	**Study design:** randomized controlled trial **Study grouping:** 2 groups, monoprophylaxis
Participants	**Baseline characteristics** Dexamethasone • *Assessed for eligibility (n)*: - • *Enrolled (n)*: - • *Randomized (n)*: NA • *Received treatment (n)*: NA • *Analysed (n)*: 30 • *Age (mean ± SD, median (IQR), median (range))*: 42.8 ± 9.9 • *Weight (mean ± SD, median (IQR), median (range))*: 72.8 ± 10.1 • *BMI (mean ± SD, median (IQR), median (range))*: NA • *ASA I/II/III/IV (n)*: 24/6/0/0 • *Gender (female in %)*: 76.7

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Arslan 2011 *(Continued)*

- *Non-smoker (%)*: 63.3
- *History of PONV/motion sickness (%)*: 0
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane, remifentanil)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 105.5
- *Use of perioperative opioids (if yes, which?)*: intraoperative remifentanil infusion 0.2 µg/kg
- *Type of surgery*: laparoscopic cholecystectomy

Metoclopramide

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: NA
- *Received treatment (n)*: NA
- *Analysed (n)*: 30
- *Age (mean ± SD, median (IQR), median (range))*: 41.5 ± 7.8
- *Weight (mean ± SD, median (IQR), median (range))*: 70.5 ± 8.1
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 25/5/0/0
- *Gender (female in %)*: 83.3
- *Non-smoker (%)*: 70.0
- *History of PONV/motion sickness (%)*: 0
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane, remifentanil)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 110.5
- *Use of perioperative opioids (if yes, which?)*: intraoperative remifentanil infusion 0.2 µg /kg
- *Type of surgery*: laparoscopic cholecystectomy

Included criteria: patients scheduled for laparoscopic cholecystectomy (25 to 55 years of age; 48 women) with an American Society of Anesthesiologists (ASA) physical status classification system risk of I or II

Excluded criteria: history of hepatic, renal, or cardiovascular disease; chronic obstructive pulmonary disease; haematological or gastrointestinal disorders, or both; hypersensitivity to propofol or to any other drug; history of vertigo or motion sickness; previous postoperative emesis; pregnant or breastfeeding or menstruating women; use of an antiemetic agent within 24 hours before surgery; laparoscopy replaced by laparotomy

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness): no; (perioperative opioids): unclear

Interventions	**Intervention characteristics** Dexamethasone • *Dose*: 2 × 8 mg • *Time point of administration*: at induction of anaesthesia and at time to skin closure • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 20% (metoclopramide 10 mg) Metoclopramide • *Dose*: 0.2 mg/kg • *Time point of administration*: at time to skin closure (metoclopramide) • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 46.7% (metoclopramide 10 mg)
Outcomes	*Vomiting (0 to 4 hours)* • Outcome type: dichotomous outcome

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Arslan 2011 *(Continued)*

Vomiting (4 to 12 hours))

- Outcome type: dichotomous outcome

PONV (0 to 24 hours)

- Outcome type: dichotomous outcome

Adverse events (general notes in the publication, 24 hours' observation)

- Outcome type: general notes on side effects

Identification	**Sponsorship source:** NA **Country:** Turkey **Setting:** inpatient, single-centre **Author's name:** Mustafa Arslan **Institution:** Gazi University Faculty of Dentistry, Anesthesiology and Reanimation Specialist, Department of Oral and Maxillofacial Surgery **Email:** mustarslan@gmail.com **Address:** Gazi University Faculty of Dentistry, Anesthesiology and Reanimation Specialist, Department of Oral and Maxillofacial Surgery, Emek 06510 Ankara, Turkey **Duration of study:** NA **Language:** English **Study's primary outcome:** primary end point of this study was total PONV rate up to 24 hours post anaesthesia **Trial registry number:** NA
Notes	None&&

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "using a computer-generated random number table"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "patients, the anesthesiologist attending during surgery, and the anesthesiologist who collected postoperative data were all blinded to the randomization process and the identity of the study drugs"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "patients, the anesthesiologist attending during surgery, and the anesthesiologist who collected postoperative data were all blinded to the randomization process and the identity of the study drugs"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "a total of 64 patients were approached for study inclusion, 4 of whom were excluded based on criteria described previously"

- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: TIVA
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 72.9
- *Use of perioperative opioids (if yes, which?)*: fentanyl 2 mg/kg for induction, fentanyl 0.4 µg/kg/min for maintenance
- *Type of surgery*: gynaecological laparoscopic surgery such as tubal ligation, myomectomy, or ovarian cystectomy

Included criteria: women classified as American Society of Anesthesiology (ASA) physical status I or II, lack of allergy to metoclopramide, no use of antidepressants or antiemetics in 24 hours before surgery

Excluded criteria: pregnant or lactating women; weight over 90 kg; conditions such as malignant hypertension, hepatic dysfunction, pheochromocytoma, and seizure; symptoms of extrapyramidal mechanical ileus; need for post-operation ventilator or NG tube

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia): no; (history of PONV/motion sickness, non-smoker, perioperative opioids): unclear

Interventions

Intervention characteristics

Dexamethasone

- *Dose*: 8 mg
- *Time point of administration*: after intubation
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 9.3% (metoclopramide 10 mg IM/PRN or promethazine 25 mg IM/PRN)

Metoclopramide

- *Dose*: 10 mg
- *Time point of administration*: after intubation
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 22.2% (metoclopramide 10 mg IM/PRN or promethazine 25 mg IM/PRN)

Outcomes

Adverse events (general notes in the publication, 24 hours' observation)

- Outcome type: general notes on side effects

- *BMI (mean ± SD, median (IQR), median (range))*: 31.2
- *ASA I/II/III/IV (n)*: NA
- *Gender (female in %)*: NA
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: general endotracheal anaesthesia without adjuvant neuraxial analgesia was used for all patients
- *Duration of anaesthesia or surgery (in min; as mean or median)*: NA
- *Use of perioperative opioids (if yes, which?)*: 15.1 mg equivalent hydrocodone
- *Type of surgery*: unilateral, total hip or knee arthroplasty

Included criteria: patients undergoing elective unilateral total hip or knee arthroplasty

Excluded criteria: patients with a history of poorly controlled diabetes (HgbA1c > 7.5 on pre-admission testing); steroid or immunosuppressive drug use within 6 months of surgery; renal failure, hepatic failure, or previous adverse effects from medications utilized in this study

Pretreatment: baseline characteristics (age, BMI): no; (ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness): no; (perioperative opioids): yes

Interventions	**Intervention characteristics** Ondansetron • *Dose*: 4 mg • *Time point of administration*: approximately 15 minutes before skin closure • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: ondansetron 4 mg IV, prochlorperazine 5 mg IV Dexamethasone + ondansetron • *Dose*: dexamethasone 10 mg, ondansetron 4 mg • *Time point of administration*: dexamethasone immediately before induction of anaesthesia, ondansetron approximately 15 minutes before skin closure • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: ondansetron 4 mg IV, prochlorperazine 5 mg IV Dexamethasone + ondansetron (+ dexamethasone 24 hours postoperatively) • *Dose*: dexamethasone 2 × 10 mg, ondansetron 4 mg • *Time point of administration*: dexamethasone immediately before induction of anaesthesia and 24 hours postoperatively, ondansetron approximately 15 minutes before skin closure • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: ondansetron 4 mg IV, prochlorperazine 5 mg IV
Outcomes	*Postoperative wound infection (6-month follow-up)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, at a minimum of 6-month follow-up)* • Outcome type: general notes on side effects
Identification	**Sponsorship source:** NA **Country:** USA **Setting:** inpatient, single-centre

Author's name: Joel R. Politi

Institution: Cardinal Orthopedic Institute, Columbus, OH, USA

Email: NA

Address: Cardinal Orthopedic Institute, 170 Taylor Station Road, Columbus, OH 43213, USA

Duration of study: September 2011 to February 2012

Language: English

Study's primary outcome: primary outcome measures included (1) length of hospital stay (measured as number of calendar days patient was hospitalized), (2) duration of ambulation, (3) knee ROM, (4) cumulative hydromorphone PCA use, (5) daily hydrocodone consumption, (6) patient pain scores, (7) daily rescue antiemetic consumption, (8) patient nausea/vomiting scores

Trial registry number: NA

Notes	Repetitive dose of dexamethasone in 1 group after 24 hours. Data for adverse effects not eligible for the third group

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "using a computer based random integer generator"
Allocation concealment (selection bias)	Unclear risk	Quote: "patients were randomized into one of three study groups by a research assistant who was not involved with outcome assessment" Judgement comment: insufficient information on allocation concealment
Blinding of participants and personnel (performance bias) All outcomes	High risk	Quote: "patients, physical therapists, and orthopedic surgeons were blinded to study group allocation. The anesthesiologists responsible for intra-operative management were not blinded to treatment, but were not involved in any outcome assessment"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "patients, physical therapists, and orthopedic surgeons were blinded to study group allocation. The anesthesiologists responsible for intra-operative management were not blinded to treatment, but were not involved in any outcome assessment. Nurses that administered the IV dexamethasone push at 24 hours to patients in group 3 were also not blinded, but no other study group identifiers were present to nursing staff thereafter"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "ten patients had incomplete data available, leaving 120 patients for final analysis"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Quote: "the amount of milligram equivalents of hydrocodone consumed for breakthrough analgesia was significantly more in the control group; those receiving dexamethasone at the time of operation received less than half that of controls on PODs 0, 1, and 2 (15.9 vs 4.2 P = 0.003, 47.4 vs 20.2 P = 0.000, 59.9 vs 18.7 P = 0.003, respectively). Furthermore, a continued effect was seen with administering dexamethasone at 24 hours, as group 3 consumed less total mg equivalents of hydrocodone on POD 2 than group 2 (24.4 vs 15.1 P = 0.015)"

Bailey **Institution:** Department of Anesthesiology, University of Utah School of Medicine, Salt Lake City, UT, USA **Email:** NA **Address:** Department of Anesthesiology, University of Utah School of Medicine, 50 North Medical Drive, Salt Lake City, UT 84132, USA **Duration of study:** NA **Language:** English **Study's primary outcome:** NA **Trial registry number:** NA
Notes	Transdermal scopolamine for 3 days

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Judgement comment: quote: "randomized fashion" No further information on sequence generation provided
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Bailey 1990 *(Continued)*

Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding provided ("double-blind")
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding provided ("double-blind")
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Judgement comment: quote: "one hundred ninety-one patients were enrolled into the study; 53 patients were excluded from analysis because of a breach in the study protocol. Reasons for the removal of these subjects from evaluation included failure to apply the patch (n=17), patch removal either before surgery (n=5) or within 6 h after surgery (n=2), drugs with potential antiemetic effect given intraoperatively (n= 21), epidural instead of general anesthesia (n=1), non-abdominal surgery (n=3), and cancellation of surgery (n=3). In addition, one patient received no fentanyl. There was no difference between active (n=27) and placebo (n=26) groups with respect to subject removal from analysis. When appropriate, data from these patients were included in the analysis of side effects" Dropouts 27.74% (> 15%), but reasons reported. Participants seem to have problems applying the patch
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Judgement comment: baseline characteristics (age, ASA): no; (weight, BMI): unclear. Potential effect modifiers (gender, duration of anaesthesia): no; (history of PONV/motion sickness, non-smoker, perioperative opioids): unclear

Duration of study: June 2013 to January 2014

Language: English

Study's primary outcome: overall incidence of PONV during first 24 hours, defined as any episode of vomiting or nausea

Trial registry number: NCT01876290

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "the sequence of treatment with dexamethasone and ondansetron (DO group) or placebo (Placebo group) was determined in blocks of 10 (five DO and five Placebo group) using an internet-based randomisation system in a 1:1 ratio"
Allocation concealment (selection bias)	Low risk	Quote: "the sequence of treatment with dexamethasone and ondansetron (DO group) or placebo (Placebo group) was determined in blocks of 10 (five DO and five Placebo group) using an internet-based randomisation system in a 1:1 ratio. The randomisation system gave the assignment to the pharmacy 1 h prior to induction of anaesthesia" Quote: "written informed consent was obtained during the preoperative visit performed by the investigators"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the drugs or placebo [was] prepared in the pharmacy in a volume of 10 ml and [was] colourless and indistinguishable"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Judgement comment: no statement on outcome assessors Blinding of outcome assessors assumed due to the central allocation system and indistinguishable appearance of syringes
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "among 130 obese patients who were approached, 122 were recruited between June 2013 and January 2014. Usable data were obtained from 58 patients in the DO group and 59 patients in the Placebo group (Fig. 1)" Judgement comment: reasons for missing outcome data described and unrelated to outcomes of interest
Selective reporting (reporting bias)	Unclear risk	Judgement comment: NCT01876290 (retrospective registration)
Other bias	Low risk	Quote: "baseline characteristics and risk factors for PONV were similar between the two groups; median of BMI was greater than 40 kg/m^2 in both the groups (Table 1)"

Baxendale 1993 *(Continued)*

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "randomisation and preparation of dexamethasone or placebo powders were undertaken by the Pharmacy Department" Judgement comment: no information on sequence generation provided
Allocation concealment (selection bias)	Low risk	Judgement comment: central randomisation and allocation
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "patient randomisation and preparation of dexamethasone or placebo powders were undertaken by the Pharmacy Department" Judgement comment: blinding ensured (central randomisation, allocation, preparation of drugs)
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Judgement comment: blinding ensured (central randomisation, allocation, preparation of drugs)
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "one patient in the dexamethasone group was omitted from the study as only two teeth were removed"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Quote: "there were no differences between the groups in respect of gender, age, weight, or duration of surgery (Table I)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia): no; (history of PONV/motion sickness, non-smoker): unclear; (perioperative opioids): yes

Notes	Eight groups were pooled into 4 groups (menstrual and non-menstrual groups with same doses pooled for analysis)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Judgement comment: quote: "randomized study drug" No information on sequence generation provided
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding provided ("double-blind")
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Judgement comment: quote: "nausea or vomiting was recorded in a blinded manner"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV): no; (history of motion sickness, non-smoker, perioperative opioids): unclear

Participants

Baseline characteristics

Ondansetron (Group O)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 32
- *Received treatment (n)*: 31
- *Analysed (n)*: 30
- *Age (mean ± SD, median (IQR), median (range))*: 34 ± 8
- *Weight (mean ± SD, median (IQR), median (range))*: 118.7 ± 23.1
- *BMI (mean ± SD, median (IQR), median (range))*: 43.3 ± 7.4
- *ASA I/II/III/IV (n)*: 1/26/3/0
- *Gender (female in %)*: 70
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: balanced anaesthesia (propofol, remifentanil, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 154
- *Use of perioperative opioids (if yes, which?)*: remifentanil and fentanyl (3 mg/kg) intraoperative, morphine 8.8 mg
- *Type of surgery*: laparoscopic sleeve gastrectomy

Dexamethasone + ondansetron (Group DO)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 32
- *Received treatment (n)*: 32
- *Analysed (n)*: 30
- *Age (mean ± SD, median (IQR), median (range))*: 38 ± 11
- *Weight (mean ± SD, median (IQR), median (range))*: 116.5 ± 25.1
- *BMI (mean ± SD, median (IQR), median (range))*: 41.9 ± 5.6
- *ASA I/II/III/IV (n)*: 0/27/3/0
- *Gender (female in %)*: 63.3
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: balanced anaesthesia (propofol, remifentanil, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 142
- *Use of perioperative opioids (if yes, which?)*: remifentanil and fentanyl (3 mg/kg) intraoperative, morphine 7.8 mg
- *Type of surgery*: laparoscopic sleeve gastrectomy

Haloperidol + dexamethasone + ondansetron (Group HDO)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 32
- *Received treatment (n)*: 31
- *Analysed (n)*: 30
- *Age (mean ± SD, median (IQR), median (range))*: 37 ± 10
- *Weight (mean ± SD, median (IQR), median (range))*: 111.9 ± 15.4
- *BMI (mean ± SD, median (IQR), median (range))*: 41.3 ± 3.8
- *ASA I/II/III/IV (n)*: 0/30/0/0

Benevides 2013 *(Continued)*

- *Gender (female in %)*: 70
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: balanced anaesthesia (propofol, remifentanil, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 146
- *Use of perioperative opioids (if yes, which?)*: remifentanil and fentanyl (3 mg/kg) intraoperative, morphine 4.4 mg
- *Type of surgery*: laparoscopic sleeve gastrectomy

Included criteria: patients over 18 years of age, ASA status I to III, body mass index (BMI) ≥ 35 kg/m^2, scheduled to undergo laparoscopic sleeve gastrectomy

Excluded criteria: patients with hypersensitivity or contraindication to haloperidol, dexamethasone, or ondansetron; any serious complications in the perioperative period (such as shock, cardiac arrest, haemorrhage needing transfusion); psychiatric disorder; history of migraine; use of opoid, hormonal anti-inflammatory, and antiemetic medication 24 hours before surgery

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia): no; (history of PONV/motion sickness, non-smoker -> no difference in the distribution of Apfel risk factors between the groups): unclear; (perioperative opioids): yes

Interventions

Intervention characteristics

Ondansetron (Group O)

- *Dose*: 8 mg
- *Time point of administration*: 20 to 30 minutes before end of operation
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 20% (metoclopramide 10 mg IV)

Dexamethasone + ondansetron (Group DO)

- *Dose*: dexamethasone 8 mg, ondansetron 8 mg
- *Time point of administration*: dexamethasone immediately after induction of anaesthesia, ondansetron 20 to 30 minutes before end of operation
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 40% (metoclopramide 10 mg IV)

Haloperidol + dexamethasone + ondansetron (Group HDO)

- *Dose*: haloperidol 2 mg, dexamethasone 8 mg, ondansetron 8 mg
- *Time point of administration*: haloperidol and dexamethasone immediately after induction of anaesthesia, ondansetron 20 to 30 minutes before end of operation
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 50% (metoclopramide 10 mg IV)

Outcomes

Vomiting (0 to 2 hours, PACU)

- Outcome type: dichotomous outcome

Vomiting (2 to 12 hours)

- Outcome type: dichotomous outcome

Adverse events (general notes in the publication, 36 hours' observation)

- Outcome type: general notes on side effects

Email: mmmmb@terra.com.br

Address: Department of Surgery, Medical School, Federal University of Mato Grosso, Cuiabá, Mato Grosso, Brazil

Duration of study: January to October 2011

Language: English

Study's primary outcome: primary endpoints of the study were occurrence of PONV, time to first administration of rescue antiemetic drug, and number of rescues

Trial registry number: RBR-4bxdhb

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "randomization lists were computer-generated. In the operating room, sealed envelopes containing the groups were opened"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: it is not clear who performed randomization and allocation Not stated sequentially numbered, opaque, sealed envelopes (SNOSE)
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the patients, anesthesiologists, and surgeons were unaware of the randomization process and the types of drugs used"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "data collection was done by blinded personnel"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "one hundred three patients were recruited for the study. Ninety-six patients were randomized to the study. One patient was excluded due to conversion to laparotomy and another patient was excluded due to cancelation of the operation. Three patients were excluded due to loss of follow-up, and two patients were excluded due to postoperative complications (one case for upper digestive hemmorage and another for dehiscence of the suture line requiring reoperation). Another patient was excluded for having allergy to dipyrone (angioedema). One patient was excluded from analysis for having received droperidol (protocol violation). Of these 90 patients, three patients in group O and four in group HDO were discharged prior to completing the postoperative follow-up at 36 h"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: RBR-4bxdhb (retrospective registration)
Other bias	High risk	Quote: "there were no significant differences between groups regarding patient demographics, ASA physical status, Apfel score, duration of preoperative

Bergese 2016 *(Continued)*

- *Duration of anaesthesia or surgery (in min; as mean or median)*: 345 mg morphine, fentanyl 0.75 to 1.5 µg/kg IV + boluses of 0.5 to 2.0 µg/kg IV
- *Use of perioperative opioids (if yes, which?)*: 75.0
- *Type of surgery*: elective craniotomy

Included criteria: neurosurgical patients whose ages ranged from 18 to 85 years, American Society of Anesthesiologist (ASA) physical status of I to III, scheduled to undergo elective craniotomy (opening of the cranium and dura mater) requiring at least 1 hour of general anaesthesia, moderate to severe risk for PONV as assessed by having 2 or more risk factors on the simplified Apfel score

Excluded criteria: prisoners or mentally ill people, past medical history of alcohol or drug abuse, history of allergy reaction or intolerance to any study medications, pregnant or breastfeeding women, history of nausea and/or vomiting within 24 hours of procedure, history of treatment with antiemetic medication for nausea or vomiting within 24 hours of procedure, history of chemotherapy treatment within 4 weeks before surgery. Only patients having craniotomy procedures and requiring admission were included. Patients who had received any medication with antiemetic properties before surgery

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Interventions	**Intervention characteristics** Aprepitant + promethazine + dexamethasone • *Dose*: aprepitant 40 mg, promethazine 25 mg, dexamethasone 10 mg, placebo • *Time point of administration*: aprepitant 30 to 60 minutes before induction of anaesthesia; placebo, promethazine, and dexamethasone at induction of anaesthesia • *Route of administration*: aprepitant: oral, placebo, promethazine, and dexamethasone IV • *Rescue antiemetics (if yes, which?)*: 44% (choice left to investigator's discretion) Ondansetron + promethazine + dexamethasone • *Dose*: ondansetron 4 mg, promethazine 25 mg, dexamethasone 10 mg, placebo • *Time point of administration*: placebo pill 30 to 60 minutes before induction of anaesthesia; ondansetron, promethazine, and dexamethasone at induction of anaesthesia • *Route of administration*: placebo pill oral, ondansetron, promethazine, and dexamethasone IV • *Rescue antiemetics (if yes, which?)*: 53% (choice left to investigator's discretion)
Outcomes	*Vomiting (0 to 24 hours)* • Outcome type: dichotomous outcome *Nausea (0 to 24 hours)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 5-day follow-up)* • Outcome type: general notes on side effects
Identification	**Sponsorship source:** this research pilot study was funded by The Ohio State University Medical Center, Department of Anesthesiology **Country:** USA **Setting:** inpatient, single-centre **Author's name:** Alberto A. Uribe **Institution:** Department of Anesthesiology, The Ohio State University Wexner Medical Center, Columbus, OH, USA

Duration of study: January 2009 to April 2012

Language: English

Study's primary outcome: incidence of PONV

Trial registry number: NCT01474915

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "the method used for randomization was simple randomization using a random list generator"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the health-care providers and researchers were blinded throughout the study, the only unblinded personnel was the pharmacist who prepared the study drug based on the randomization list"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "the health-care providers and researchers were blinded throughout the study, the only unblinded personnel was the pharmacist who prepared the study drug based on the randomization list"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "total of 121 subjects were screened and enrolled to participate in this study. However, 6 subjects were considered screen failures due to failure to meet inclusion criteria or meeting exclusion criteria, and 20 subjects were removed from the study due to protocol deviations that could affect our data analysis. Deviations from the protocol included anesthesia care staff not administrating the triple therapy as directed, prolonged intubation after surgery, and/or loss of follow-up. Ninety-five subjects completed the study: 48 in the aprepitant group and 47 in the ondansetron group"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: NCT01474915 (retrospective registration)
Other bias	Low risk	Quote: "there were no statistically significant differences among subjects' demographics, risk factors for PONV, duration of anaesthesia, and postoperative opioid consumption between the two groups (Table 1)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Bestas 2007 *(Continued)*

- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA/NA/0/0
- *Gender (female in %)*: 77
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 0
- *Type of general anaesthesia*: inhalational anaesthesia (isoflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 85.5
- *Use of perioperative opioids (if yes, which?)*: 154.1 µg fentanyl intraoperative + 113.3 µg fentanyl post-operative
- *Type of surgery*: laparoscopic cholecystectomy

Included criteria: consecutive adult patients of both sexes classified as American Society of Anesthesiologists physical status I or II, scheduled for elective laparoscopic cholecystectomy

Excluded criteria: patients with history of PONV and/or motion sickness; patients who were pregnant, lactating, or menstruating; those with clinically notable gastrointestinal, cardiovascular, neurological, renal, hepatic, or endocrinological disease (e.g. obesity, diabetes mellitus); those receiving drugs with known antiemetic effects

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness, perioperative opioids): no; (non-smoker): unclear

Interventions	**Intervention characteristics** Ondansetron • *Dose*: 100 µg /kg • *Time point of administration*: approximately 20 to 30 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 30% (metoclopramide 10 mg) Granisetron • *Dose*: 40 µg /kg • *Time point of administration*: approximately 20 to 30 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 20% (metoclopramide 10 mg) Placebo • *Dose*: saline • *Time point of administration*: approximately 20 to 30 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 60% (metoclopramide 10 mg)
Outcomes	*Complete response (no PONV) in 24 hours* • Outcome type: dichotomous outcome *Headache (0 to 24 hours)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 24 hours' observation)* • Outcome type: general notes on side effects

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "patients were randomized" Judgement comment: no further information on sequence generation provided
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "all study drugs (ondansetron 100 µg/kg, granisetron 40 µg/kg, and normal saline) were diluted by a nurse anesthetist to a fixed volume of 100 ml and marked with a coded label to ensure the double-blind nature of the study"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "all patients were observed in the recovery room during the first postoperative hour and then in the ward by the same investigator (A.Y.) who was blinded to the treatment groups"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "ninety patients (69 women, 21 men) were included in the study. There were 30 patients in each group, and all of the patients completed the study"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "there were no significant differences between the 3 groups in regard to demographic characteristics, mean duration of surgery, mean duration of anesthesia, or intraoperative total fentanyl consumption (Table I)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness, perioperative opioids): no; (non-smoker): unclear

- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 16.67/13.33
- *Type of general anaesthesia*: inhalational anaesthesia (isoflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 141
- *Use of perioperative opioids (if yes, which?)*: fentanyl 2 µg/kg for induction, 9 patients with postoperative tramadol 100 mg, no patients with morphine 3 mg within 2 hours
- *Type of surgery*: modified radical mastectomy

Included criteria: ASA physical status I and II, hospitalised female patients, 18 to 65 years of age, scheduled for modified radical mastectomy

Excluded criteria: patients with gastrointestinal (GI) disease (e.g. hiatal hernia, gastro-oesophageal regurgitation disorder, non-ulcerative dyspepsia, peptic ulcer disease, and autonomic dysfunction disorder); those who were menstruating; those who had received any antiemetic medication within 24 hours of surgery

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness, perioperative opioids): no; (non-smoker): unclear

Interventions	**Intervention characteristics** Placebo • *Dose*: placebo • *Time point of administration*: 1 hour before induction of anaesthesia • *Route of administration*: PO • *Rescue antiemetics (if yes, which?)*: ondansetron 4 mg IV Granisetron • *Dose*: 2 mg • *Time point of administration*: 1 hour before induction of anaesthesia • *Route of administration*: PO • *Rescue antiemetics (if yes, which?)*: ondansetron 4 mg IV Ondansetron • *Dose*: 4 mg • *Time point of administration*: 1 hour before induction of anaesthesia • *Route of administration*: PO • *Rescue antiemetics (if yes, which?)*: ondansetron 4 mg IV
Outcomes	*Vomiting (0 to 2 hours)* • Outcome type: dichotomous outcome *Vomiting (2 to 6 hours)* • Outcome type: dichotomous outcome *Subjects with any AE (0 to 2, 2 to 6, 6 to 12, 12 to 24 hours)* • Outcome type: dichotomous outcome *Headache (0 to 2, 2 to 6, 6 to 12, 12 to 24 hours)* • Outcome type: dichotomous outcome *Sedation/drowsiness (0 to 2, 2 to 6, 6 to 12, 12 to 24 hours)*

- *Type of surgery*: major gynaecological surgery

Included criteria: women scheduled for major gynaecological surgery under general anaesthesia

Excluded criteria: younger than 18 years of age; weight > 100 kg; ASA IV or V, nausea; vomiting or antiemetic therapy during the last 24 hours before application of study drug; contraindications against ondansetron; history of drug or alcohol abuse; pregnancy or breastfeeding

Pretreatment: baseline characteristics (age, weight): no; (ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia, history of PONV): no; (history of motion sickness, non-smoker, peri-operative opioids): unclear

Interventions	**Intervention characteristics** Ondansetron • *Dose*: 8 mg • *Time point of administration*: before anaesthesia induction • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 28% (ondansetron 4 mg and additional other antiemetics) Placebo • *Dose*: saline • *Time point of administration*: before anaesthesia induction • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 47% (ondansetron 4 mg and additional other antiemetics)
Outcomes	*Vomiting (0 to 24 hours)* • Outcome type: dichotomous outcome *Nausea (0 to 24 hours)*

Bisgaard 2003 *(Continued)*

Included criteria: NA

Excluded criteria: ASA III or IV; over 75 years of age; pregnancy; having papillotomy by endoscopic retrograde cholangiopancreatography (ERCP) within 1 month before and during first month after operation; chronic pain disease other than gallstone disease; any signs of endocrine, renal, hepatic, or immunological disease; or received opioids or tranquillizers (treatment of over 1 week before LC); foreign language or mental disorder; history of alcohol or drug abuse; operation converted from LC to open procedure or additional fifth trocar needed to complete the operation. Finally, because development of surgical complications might influence chosen outcome parameters, we decided before study start to exclude these patients from the study and we analysed results by protocol

Pretreatment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness): no; (perioperative opioids): yes

Interventions

Intervention characteristics

Dexamethasone

- *Dose*: 8 mg
- *Time point of administration*: 90 minutes before surgery
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 53.33% (ondansetron 4 mg IV)

Placebo

- *Dose*: -
- *Time point of administration*: 90 minutes before surgery
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 37.5% (ondansetron 4 mg IV)

Outcomes

Vomiting (0 to 24 hours)

- Outcome type: dichotomous outcome

Vomiting (0 to 6 hours)

- Outcome type: dichotomous outcome

Vomiting (6 to 24 hours)

- Outcome type: dichotomous outcome

Nausea (0 to 24 hours)

- Outcome type: dichotomous outcome

Postoperative wound infection (0 to 7 days)

- Outcome type: dichotomous outcome

Adverse events (general notes in the publication, 30 days' follow-up)

- Outcome type: general notes on side effects

Identification

Duration of study: February 1999 to November 2000

Language: English

Study's primary outcome: primary endpoints were fatigue and pain

Trial registry number: NA

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "patients were randomized by the sealed envelope method (on the basis of a block-randomized computer-generated list)"
Allocation concealment (selection bias)	Unclear risk	Quote: "patients were randomized by the sealed envelope method (on the basis of a block-randomized computer-generated list), and the randomization code was kept separate and not known to any of the investigators until the study was finished" Judgement comment: not stated; "sequentially numbered, opaque, sealed envelopes" (SNOSE)
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the drug/placebo solution was drawn into a syringe by a nurse not participating in the study and was delivered to the investigator (TB) who was outside the medicine room and unaware of the content. The saline and dexamethasone solutions appeared transparent and completely identical at the time syringes were given to the investigator. Thus, the patient, the anesthesiologist, the surgeon, and the study observer were all blinded with respect to the study group"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "thus, the patient, the anesthesiologist, the surgeon, and the study observer were all blinded with respect to the study group"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "the study drugs were observed. Four patients in each study group were excluded from the study. In the dexamethasone group, 2 patients had cholecystectomy performed using an additional trocar (5-port cholecystectomy), since a laparoscopic paddle retractor was used to lift the liver to avoid conversion to open procedure. In 1 patient, preoperative cholangiography revealed a retained stone in the common bile duct, and endoscopic retrograde cholangiography (ERCP) with stone extraction was performed the next day. One patient developed an infection in the umbilical incision (skin opened 5 days after operation). In the placebo group, the operation was converted to open procedure in 2 patients (due to dense abdominal adhesions), 1 patient withdrew from the study postoperatively, and 1 patient developed an infection in the umbilical incision (skin opened 6 days after)"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Quote: "with a significantly lower total dose of morphine in the dexamethasone group"

Bisgaard 2008 *(Continued)*

	Included criteria: undergoing elective laparoscopic cholecystectomy, incorrect timing of tablet intake not considered a protocol violation. Patients with postoperative complications were also included in the analysis **Excluded criteria:** ASA physical class IV, younger than 18 and over 75 years of age, pregnancy. Patients were not included if they had chronic pain disease other than gallstone disease; history of or any signs of endocrine, renal, hepatic, or immunological disease; received opioids or tranquilizers (treatment for 1 week before laparoscopic cholecystectomy); foreign language or mental disorder; history of alcohol or drug abuse. Patients were excluded from the study (and study data were not collected) if the operation was converted from a laparoscopic to an open procedure. Patients were also excluded in the case of protocol violation (ingestion of none or only 1 study drug tablet), whereby incorrect timing of tablet intake (see below) was not considered a protocol violation **Pretreatment:** baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, perioperative opioids): no; (history of PONV/motion sickness, non-smoker): unclear
Interventions	**Intervention characteristics** Prednisolone • *Dose*: 50 mg • *Time point of administration*: 2 hours before laparoscopic cholecystectomy • *Route of administration*: oral • *Rescue antiemetics (if yes, which?)*: 27.66% (ondansetron 1 mg, dehydrobenzperidol 0.612 mg) Placebo • *Dose*: placebo tablets • *Time point of administration*: 2 hours before laparoscopic cholecystectomy • *Route of administration*: oral • *Rescue antiemetics (if yes, which?)*: 41.11% (ondansetron 1 mg, dehydrobenzperidol 0.612 mg)
Outcomes	*Vomiting (0 to 24 hours)* • Outcome type: dichotomous outcome *Vomiting (0 to 6 hours)* • Outcome type: dichotomous outcome *Vomiting (6 to 24 hours)* • Outcome type: dichotomous outcome *Nausea (0 to 24 hours)* • Outcome type: dichotomous outcome *Postoperative wound infection (1 week)* • Outcome type: dichotomous outcome *Headache (one week)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 1 week of observation)* • Outcome type: general notes on side effects
Identification	**Sponsorship source:** study authors would like to thank Nycomed Danmark A/S, Denmark, for providing randomized concealed containers of study drugs for the trial

Duration of study: September 2003 to March 2005

Language: English

Study's primary outcome: primary outcome was pain 24 hours after operation

Trial registry number: NA

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "patients were consecutively enrolled in the trial by the medical staff in the ambulatory unit and block-randomized by the manufacturer (Nycomed Danmark A/S)" Judgement comment: previous study (Bisgaard-2008) described the same study design and used a computer-generated list. We assumed the same procedure here
Allocation concealment (selection bias)	Low risk	Quote: "the study drugs were delivered in sealed indistinguishable containers bearing random numbers" Judgement comment: central allocation
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "boxes contained either two tablets of prednisone (25 mg each, total of 50 mg) or two placebo tablets of identical appearances. Patients were instructed to ingest the two tablets 2 h before the scheduled operation time. The randomization code was kept separate from the investigators by the manufacturer"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "the randomization code was kept separate from the investigators by the manufacturer. The sequence was concealed until data analysis was completed more than 1 month after ending the study"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "in total, 184 patients were available for analysis and 16 patients (6 and 10 in the prednisone and placebo groups, respectively) were excluded from the study analysis (Fig. 1). Patient data were not available in nine patients due to the loss of the patient diary, four patients were converted to open procedure, one patient refused to participate after ingestion of the study tablets, one patient violated the study protocol, and one patient had the operation cancelled after the ingestion of the study tablets"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Bisgaard 2008 *(Continued)*

Other bias	Unclear risk	Quote: "there were no significant differences between the study groups except for the time interval between intake of tablets and operation [170 min (prednisone) versus 163 min (placebo)" Judgement comment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, perioperative opioids): no; (history of PONV/motion sickness, non-smoker): unclear

Trial registry number: NA

Study's primary outcome: complete response

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "using a random number table"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "study medications were prepared by personnel not involved in this study in identical 5 ml syringes to ensure blinding of the anesthetists"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "patients and investigators who collected postoperative data were blinded to the study drug administered"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to study protocol or trial registry number reported
Other bias	Low risk	Quote: "the treatment groups were comparable with regard to patient demographics and types of operation" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Participants

Baseline characteristics

Methylprednisolone

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 59
- *Received treatment (n)*: 59
- *Analysed (n)*: 49
- *Age (mean ± SD, median (IQR), median (range))*: 68 (61 to 75)
- *Weight (mean ± SD, median (IQR), median (range))*: NA
- *BMI (mean ± SD, median (IQR), median (range))*: 21.2 ± 4.0
- *ASA I/II/III/IV (n)*: 3/30/23/0
- *Gender (female in %)*: 64
- *Non-smoker (%)*: 77
- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: TIVA (propofol/remifentanil)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 104
- *Use of perioperative opioids (if yes, which?)*: remifentanil for anaesthesia, 5 mg morphine postoperative day 0, 0 mg morphine postoperative day 1, 0 mg morphine postoperative day 2
- *Type of surgery*: elective VATS lobectomy

Placebo

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 60
- *Received treatment (n)*: 60
- *Analysed (n)*: 47
- *Age (mean ± SD, median (IQR), median (range))*: 66.5 (60 to 73)
- *Weight (mean ± SD, median (IQR), median (range))*: NA
- *BMI (mean ± SD, median (IQR), median (range))*: 21.8 ± 3.9
- *ASA I/II/III/IV (n)*: 8/18/30/0
- *Gender (female in %)*: 47
- *Non-smoker (%)*: 74
- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: TIVA (propofol/remifentanil)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 102
- *Use of perioperative opioids (if yes, which?)*: remifentanil for anaesthesia, 5 mg morphine postoperative day 0, 0 mg morphine postoperative day 1, 0 mg morphine postoperative day 2
- *Type of surgery*: elective VATS lobectomy

Included criteria: consenting patients over 18 years of age who underwent elective VATS lobectomy at the Department of Cardiothoracic Surgery, Rigshospitalet, Copenhagen University Hospital, Denmark

Excluded criteria: inability to cooperate; inability to speak or understand Danish; no planned follow-up at Rigshospitalet; allergies to any used medicines; symptomatic gastric ulceration; New York Heart Association functional classification of III or more; preoperative increased plasma creatinine; pharmacologically treated diabetes mellitus; abuse of medicine or alcohol (over 5 units/d); use of psychopharmacological agents, systemic steroids (except inhalations), and/or opioid agonists; neurological deficits affecting pain perception; previous ipsilateral pulmonary resection; pregnant and/or breastfeeding. Included patients were withdrawn if they were re-operated on within 72 hours, had massive intrathoracic adherences, deviated from the standard postoperative analgesia, converted to thoracotomy, and/or breached protocol rules

Bjerregaard 2018 *(Continued)*

Random sequence generation (selection bias)	Low risk	Quote: "computer-generated randomization sequence"
Allocation concealment (selection bias)	Low risk	Quote: "before the start of the study, 100 sealed opaque envelopes were prepared by persons with no relation to the study" Judgement comment: quote: "opened the next envelope"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "patients, caregivers and investigators were blinded to group assignment" Quote: "...depending on the enclosed information. The syringe was blinded by a plaster bandage and brought to the investigator who administered the medicine to the patient after induction of anaesthesia..."
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "patients, caregivers and investigators were blinded to group assignment" Quote: "postoperative pain, nausea and sedation were scored by trained nurses every 3rd hour from arrival in the PACU until midnight on the day of surgery"
Incomplete outcome data (attrition bias) All outcomes	High risk	Quote: "one (1%) patient withdrew informed consent and 23 (19%) patients were withdrawn by the investigators, leaving 96 (80%) patients for the final analysis" Judgement comment: high rate of missing data. Participants withdrawn by investigators > 15%, but reasons described and unrelated to outcomes of interest
Selective reporting (reporting bias)	Low risk	Judgement comment: EUCTR2012-004451-37 (prospective registration). The prospectively registered primary outcome (pain) was reported in the pre-specified way in the final study report. The primary outcome was not PONV-related
Other bias	Unclear risk	Quote: "baseline characteristics and perioperative data are presented in Tables 2 and 3, and with the exception of gender, these showed an acceptable balance between the groups" Judgement comment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, perioperative opioids): no; (history of PONV/motion sickness): unclear

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "randomization was performed by the pharmacy using a computer-generated randomization process"
Allocation concealment (selection bias)	Low risk	Quote: "these bubble packs were specifically designed by the pharmacy to ensure that each capsule looked alike and to ensure that both investigators and subjects were blind to the actual contents until the conclusion of the study. The pharmacy maintained a master list as to the actual contents of the capsules" Quote: "the study medication was prepared before initiation of this study by the pharmacy, which created 88 “bubble packs,” each containing 2 capsules of either 50 mg of meclizine or placebo. These bubble packs were specifically designed by the pharmacy to ensure that each capsule looked alike" Judgement comment: central allocation
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "individual group assignment was not divulged to the subjects or investigators until conclusion of the study"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "individual group assignment was not divulged to the subjects or investigators until conclusion of the study"
Incomplete outcome data (attrition bias) All outcomes	High risk	Judgement comment: high dropout rates (> 15%)
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "no significant differences were demonstrated between the meclizine and control groups with regard to demographic variables (gender, age, height, and weight), risk factors for PONV, anesthesia and surgical times, and preoperative and postoperative sleepiness scale scores (Table) or in the number of laparoscopic procedures performed" Judgement comment: baseline characteristics (age, weight): no; (ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness): no; (perioperative opioids): unclear

Broome 1999 *(Continued)*

- *Age (mean ± SD, median (IQR), median (range))*: 26.0 ± 5.1
- *Weight (mean ± SD, median (IQR), median (range))*: 66.8 ± 7.4
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA/NA/0/0
- *Gender (female in %)*: 73.33
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: combined anaesthesia (enflurane, N_2O, propofol)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: NA
- *Use of perioperative opioids (if yes, which?)*: fentanyl 100 µg
- *Type of surgery*: multiple third molar tooth extractions

Ondansetron (tramadol group)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 30
- *Received treatment (n)*: NA
- *Analysed (n)*: 26
- *Age (mean ± SD, median (IQR), median (range))*: 27.1 ± 6.3
- *Weight (mean ± SD, median (IQR), median (range))*: 62.6 ± 17.1
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA/NA/0/0
- *Gender (female in %)*: 73.08
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: combined anaesthesia (enflurane, N_2O, propofol)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: NA
- *Use of perioperative opioids (if yes, which?)*: tramadol 100 mg
- *Type of surgery*: multiple third molar tooth extractions

Included criteria: 18 to 60 years of age, ASA I or II, scheduled to undergo elective multiple third molar tooth extractions as day cases

Excluded criteria: inability or unwillingness to give written consent, contraindications to the use of NSAIDs, parkinsonism or history of extrapyramidal reaction to metoclopramide or other drugs, use of other analgesics in the 12 hours before surgery, contraindications to tramadol, hypersensitivity, monoamine oxidase inhibitor therapy, severe renal or hepatic disease, epilepsy

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, perioperative opioids): no; (history of PONV/motion sickness, duration of anaesthesia, non-smoker): unclear

Interventions

Intervention characteristics

Metoclopramide (fentanyl group)

- *Dose*: 10 mg
- *Time point of administration*: after induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: prochlorperazine 12.5 mg IM up to 8-hourly

Metoclopramide (tramadol group)

- *Dose*: 10 mg
- *Time point of administration*: after induction of anaesthesia
- *Route of administration*: IV

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Broome 1999 *(Continued)*

- *Rescue antiemetics (if yes, which?)*: prochlorperazine 12.5 mg IM up to 8-hourly

Ondansetron (fentanyl group)

- *Dose*: 4 mg
- *Time point of administration*: after induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: prochlorperazine 12.5 mg IM up to 8-hourly

Ondansetron (tramadol group)

- *Dose*: 4 mg
- *Time point of administration*: after induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: prochlorperazine 12.5 mg IM up to 8-hourly

Outcomes	*Vomiting (0 to 2 hours)* • Outcome type: dichotomous outcome *Vomiting (2 to 24 hours)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 24 hours' observation)* • Outcome type: general notes on side effects
Identification	**Sponsorship source:** NA **Country:** UK **Setting:** outpatient, single-centre **Author's name:** G.J. Wardall **Institution:** Department of Anaesthetics, Falkirk and District Royal Infirmary, Major's Loan, Falkirk FK1 5QE, UK **Email:** NA **Address:** Department of Anaesthetics, Falkirk and District Royal Infirmary, Major's Loan, Falkirk FK1 5QE, UK **Duration of study:** NA **Language:** English **Study's primary outcome:** pain or nausea score **Trial registry number:** NA
Notes	Four groups were pooled into 2 groups (with same antiemetic medication) for analysis

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "patients were randomly allocated into four treatment groups" Judgement comment: no further information on sequence generation provided

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Broome 1999 *(Continued)*

Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding ("double-blind")
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "to ensure blinding, these were performed by an assessor who had not anaesthetised the patient and who was unaware which study drugs had been given intraoperatively"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "in all, 109 patients were recruited; 83 were female. Eleven patients were withdrawn from the study, six because of the need for more extensive surgery and five due to failure to return postdischarge questionnaires"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "there were no significant differences between the four groups with regard to age, sex or weight (Table 1)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, perioperative opioids): no; (history of PONV/motion sickness, duration of anaesthesia, non-smoker): unclear

- *Type of general anaesthesia*: inhalational anaesthesia (volatile agent, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: NA
- *Use of perioperative opioids (if yes, which?)*: NA
- *Type of surgery*: laparoscopic abdominal or gynaecological surgery

Palonosetron (0.075 mg group)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: NA
- *Received treatment (n)*: 138
- *Analysed (n)*: 138
- *Age (mean ± SD, median (IQR), median (range))*: 38 ± 11
- *Weight (mean ± SD, median (IQR), median (range))*: NA
- *BMI (mean ± SD, median (IQR), median (range))*: 28 ± 5
- *ASA I/II/III/IV (n)*: 72/62/4/0
- *Gender (female in %)*: 96
- *Non-smoker (%)*: 85
- *History of PONV/motion sickness (%)*: 66/NA
- *Type of general anaesthesia*: inhalational anaesthesia (volatile agent, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: NA
- *Use of perioperative opioids (if yes, which?)*: NA
- *Type of surgery*: laparoscopic abdominal or gynaecological surgery

Included criteria: at least 18 years of age, ASA physical status I to III, scheduled to undergo elective laparoscopic abdominal or gynaecological surgery of at least 1 hour duration. All patients had at least 2 risk factors for PONV: female gender, history of PONV and/or motion sickness, non-smoking status (never smoked or quit over 12 months ago). All patients were expected to go home on the same day that they underwent surgery

Excluded criteria: received cancer chemotherapy within 4 weeks or emetogenic radiotherapy within 8 weeks before study entry

Pretreatment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, history of PONV, non-smoker): no; (duration of anaesthesia, history of motion sickness, perioperative opioid): unclear

Interventions

Intervention characteristics

Placebo

- *Dose*: saline
- *Time point of administration*: immediately before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 52% (at the discretion of the investigator, except droperidol and palonosetron)

Palonosetron (0.025 mg group)

- *Dose*: 0.025 mg
- *Time point of administration*: immediately before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: at the discretion of the investigator, except droperidol and palonosetron

Palonosetron (0.050 mg group)

- *Dose*: 0.050 mg

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "randomization to treatment was stratified by gender, history of PONV and/or motion sickness, and smoking status. A dynamic adaptive stratification type of randomization method was used to balance the four groups across the entire study and not within each individual site"
Allocation concealment (selection bias)	Low risk	Judgement comment: central allocation
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "at each study site, palonosetron and placebo were prepared for administration to patients by an unblinded research pharmacist or designee who was otherwise not involved in the conduct of the study" Quote: "...(minutes) before induction of anesthesia. The assigned randomization number was associated with sealed cartons containing the study drug which were provided to the unblinded research pharmacist at each site"
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Judgement comment: no statement
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "six hundred thirty-nine patients were screened for this study, of which 65 were screening failures. Of the 574 remaining patients, 489 were randomized at 36 centers in the United States, and 85 were randomized at seven centers in Romania. Five hundred forty-seven patients were treated: palonosetron 0.025 mg (n 136), 0.050 mg (n 137), 0.075 mg (n 138), and placebo (n 136); 27 patients were not treated. The 48 patients who were randomized but did not complete the study were distributed across the three treatment groups and placebo group as follows: placebo (n 7), palonosetron 0.025 mg (n 18), palonoestron 0.050 mg (n 9), and palonosetron 0.075 mg (n 14). There were no statistically significant..."
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "there were no statistically significant differences in age, height, weight, body mass index, PONV risk factors, type of surgery or ASA status in patients across all treatment groups" Judgement comment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, history of PONV, non-smoker): no; (duration of anaesthesia, history of motion sickness, perioperative opioid): unclear

Study's primary outcome: primary efficacy variable was the proportion of patients defined by the presence or absence of any emetic episodes over the 24-hour period regardless of rescue treatment given

Trial registry number: NA

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "allocated randomly" Judgement comment: no further information on sequence generation provided
Allocation concealment (selection bias)	Low risk	Quote: "the study medication consisted of 5 ml ampoules containing 5 mg of tropisetron or perfectly matching placebo ampoules and was supplied to the centres in a sealed box containing a leaflet with instructions for preparation. The randomization number was printed on the box. A 5 ml syringe was prepared by the local pharmacist (in four centres) or a physician or nurse not participating in the study in any other way" Judgement comment: central allocation
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "a 5 ml syringe was prepared by the local pharmacist (in four centres) or a physician or nurse not participating in the study in any other way"
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Judgement comment: no statement
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "informed consent was obtained and study medication was prepared for a total of 391 sequential patients. The number of patients enrolled per centre varied between 33 and 70. Three patients withdrew their consent before administration of the study drug. Three ineligible patients were withdrawn from the study before administration of study medication because of a history of angioneurotic oedema, an ovarian carcinoma with metastases and a positive pregnancy test. The study medication was administered to a total of 385 patients in the 1 hour period before the start of induction. In a single patient, induction followed 125 min after study drug administration because of unexpected delay in the surgery schedule. All 385 female patients were included in the analysis"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "in this study 381 of 385 patients (99%) were white. The groups were comparable in age, weight, height, days since last menstrual cycle and propor-

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "patients were assigned by closed envelope randomization schedule to one of two groups"
Allocation concealment (selection bias)	Unclear risk	Quote: "closed envelope randomization" Judgement comment: not mentioned: "sequentially numbered, opaque, sealed envelopes (SNOSE)"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "before surgery, drugs were prepared in identical 2.5 ml syringes and coded by an anaesthesia assistant not involved in the surgery. Patients were fasted 6 hours preoperatively and after securing an intravenous line, were premedicated with intravenous ranitidine 50 mg and intravenous Midazolam 2 mg, and study drugs were administered by a blinded anaesthetist just prior to induction"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "patients were evaluated in the recovery room by an assistant who was ignorant about the coding and identity of the antiemetic drug given. When awake (judged by spontaneous"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Low risk	Quote: "value < 0.05 was considered significant. Both groups were comparable in terms of age, weight, ASA physical status and duration of surgery (table 1). The type and amount of drugs used in anaesthesia, and any intraoperative and postoperative haemodynamics which may have had an impact on PONV in these patients were also not significantly different. In the early recovery period" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Chan 1998 *(Continued)*

- *Analysed (n)*: 50
- *Age (mean ± SD, median (IQR), median (range))*: 47 (19 to 74)
- *Weight (mean ± SD, median (IQR), median (range))*: 55 (40 to 67)
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 26/24/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 38/38
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 156
- *Use of perioperative opioids (if yes, which?)*: 19.5 mg postoperative PCA morphine IV, induction morphine 0.15 mg/kg
- *Type of surgery*: radical mastectomy, lumpectomy, axillary dissection

Tropisetron (2 mg group)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 50
- *Received treatment (n)*: 50
- *Analysed (n)*: 49
- *Age (mean ± SD, median (IQR), median (range))*: 52 (29 to 75)
- *Weight (mean ± SD, median (IQR), median (range))*: 55 (35 to 73)
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 26/23/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 31/24
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 162
- *Use of perioperative opioids (if yes, which?)*: 18.5 mg postoperative PCA morphine IV, induction morphine 0.15 mg/kg
- *Type of surgery*: radical mastectomy, lumpectomy, axillary dissection

Tropisetron (5 mg group)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 50
- *Received treatment (n)*: 50
- *Analysed (n)*: 49
- *Age (mean ± SD, median (IQR), median (range))*: 45 (32 to 73)
- *Weight (mean ± SD, median (IQR), median (range))*: 53 (36 to 77)
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 30/19/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 27/29
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 156
- *Use of perioperative opioids (if yes, which?)*: 17.1 mg postoperative PCA morphine IV, induction morphine 0.15 mg/kg
- *Type of surgery*: radical mastectomy, lumpectomy, axillary dissection

Chan 1998 *(Continued)*

Included criteria: female patients with breast cancer undergoing modified radical mastectomy or lumpectomy with axillary dissection, ASA I or II, 18 to 75 years of age

Excluded criteria: patients who had preexisting nausea or vomiting or had received opioids or drugs with known antiemetic properties in the 24 hours before surgery; pregnant patients; history of oesophageal reflux or opioid or alcohol abuse

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness, perioperative opioids): no; (non-smoker): unclear

Interventions	**Intervention characteristics** Placebo • *Dose*: saline • *Time point of administration*: before induction of anaesthesia over 30 seconds • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 78% (prochlorperazine 12.5 mg) Tropisetron (2 mg group) • *Dose*: 2 mg • *Time point of administration*: before induction of anaesthesia over 30 seconds • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 55.10% (prochlorperazine 12.5 mg) Tropisetron (5 mg group) • *Dose*: 5 mg • *Time point of administration*: before induction of anaesthesia over 30 seconds • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 24.49% (prochlorperazine 12.5 mg)
Outcomes	*Vomiting (0 to 2 hours)* • Outcome type: dichotomous outcome *Vomiting (2 to 6 hours)* • Outcome type: dichotomous outcome *Complete response (no PONV) in 24 hours* • Outcome type: dichotomous outcome *Headache (early postoperative period)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 24 hours' observation)* • Outcome type: general notes on side effects
Identification	**Sponsorship source:** tropisetron was kindly supplied by Novartis Pharmaceutical, Hong Kong **Country:** China **Setting:** inpatient, single-centre **Author's name:** Matthew Chan **Institution:** Department of Anaesthesia and Intensive Care, Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, New Territories, Hong Kong

Duration of study: NA

Language: English

Study's primary outcome: incidence of PONV

Trial registry number: NA

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "computer-generated random number"
Allocation concealment (selection bias)	Unclear risk	Quote: "concealed in an envelope" Judgement comment: not mentioned: "sequentially numbered, opaque, sealed envelopes (SNOSE)"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "study drugs were prepared by an anaesthesiologist not otherwise involved in the study..."
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "patient interviews were conducted in a standardized fashion by trained nurses who were blinded to the study drug"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "forty-eight patients completed the study (placebo, n = 50; tropisetron 2 mg, y1 = 49; tropisetron 5 mg, n = 49). One patient who received tropisetron 5 mg was excluded because of missing data. Another patient who received tropisetron 2 mg was erroneously given metoclopramide just before the end of surgery and was excluded from the study. This patient continued to suffer"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "age, weight, height, and variables that may influence PONV did not differ among the groups (Table 1)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness, perioperative opioids): no; (non-smoker): unclear

Study grouping: 4 groups, monocombination and combination prophylaxis

Participants

Baseline characteristics

Placebo

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 100
- *Received treatment (n)*: 97
- *Analysed (n)*: 97
- *Age (mean ± SD, median (IQR), median (range))*: 37 (18 to 51)
- *Weight (mean ± SD, median (IQR), median (range))*: 50 (39 to 65)
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 47/50/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: 85
- *History of PONV/motion sickness (%)*: 32/18
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 56
- *Use of perioperative opioids (if yes, which?)*: 115 µg fentanyl, 4.1 mg morphine
- *Type of surgery*: laparoscopic gynaecological surgery

Ondansetron

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 100
- *Received treatment (n)*: 100
- *Analysed (n)*: 100
- *Age (mean ± SD, median (IQR), median (range))*: 32 (19 to 50)
- *Weight (mean ± SD, median (IQR), median (range))*: 52 (35 to 73)
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 51/49/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: 83
- *History of PONV/motion sickness (%)*: 12/12
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 42
- *Use of perioperative opioids (if yes, which?)*: 112 µg fentanyl, 4.4 mg morphine
- *Type of surgery*: laparoscopic gynaecological surgery

Droperidol

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 100
- *Received treatment (n)*: 98
- *Analysed (n)*: 98
- *Age (mean ± SD, median (IQR), median (range))*: 35 (18 to 77)
- *Weight (mean ± SD, median (IQR), median (range))*: 53 (36 to 77)
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA
- *Gender (female in %)*: 100

Chan 2006 *(Continued)*

- *Non-smoker (%)*: 79
- *History of PONV/motion sickness (%)*: 23/15
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 55
- *Use of perioperative opioids (if yes, which?)*: 109 µg fentanyl, 3.7 mg morphine
- *Type of surgery*: laparoscopic gynaecological surgery

Ondansetron + droperidol

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 100
- *Received treatment (n)*: 99
- *Analysed (n)*: 99
- *Age (mean ± SD, median (IQR), median (range))*: 49 (33 to 75)
- *Weight (mean ± SD, median (IQR), median (range))*: 49 (33 to 75)
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 41/58/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: 87
- *History of PONV/motion sickness (%)*: 17/17
- *Type of general anaesthesia*: inhalational anaesthesia (N_2O, isoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 48
- *Use of perioperative opioids (if yes, which?)*: 110 µg fentanyl, 3.9 mg morphine
- *Type of surgery*: laparoscopic gynaecological surgery

Included criteria: ASA I or II, between 18 and 45 years of age; scheduled for laparoscopic gynaecological surgery

Excluded criteria: preexisting nausea or vomiting; had received opioids or drugs with known antiemetic properties in the 24 hours before surgery; pregnant patients; history of oesophageal reflux, opioid or alcohol abuse

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Interventions

Intervention characteristics

Placebo

- *Dose*: saline
- *Time point of administration*: in the operating room, before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: prochlorperazine 12.5 mg IM

Ondansetron

- *Dose*: 4 mg
- *Time point of administration*: in the operating room, before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: prochlorperazine 12.5 mg IM

Droperidol

- *Dose*: 1.25 mg
- *Time point of administration*: in the operating room, before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: prochlorperazine 12.5 mg IM

Chan 2006 *(Continued)*

	Ondansetron + droperidol • *Dose*: ondansetron 4 mg, droperidol 1.25 mg • *Time point of administration*: in the operating room, before induction of anaesthesia • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: prochlorperazine 12.5 mg IM
Outcomes	*Arrhythmia (PACU)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 24 hours' observation)* • Outcome type: general notes on side effects
Identification	**Sponsorship source:** NA **Country:** China **Setting:** inpatient, single-centre **Author's name:** Matthew Chan **Institution:** Department of Anaesthesia and Intensive Care, Chinese University of Hong Kong, Prince of Wales Hospital, Hong Kong **Email:** mtvchan@cuhk.edu.hk **Address:** Department of Anaesthesia and Intensive Care, Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, New Territories, Hong Kong Special Administrative Region **Duration of study:** September 2002 and June 2004 **Language:** English **Study's primary outcome:** primary endpoint was complete response to treatment. This was defined as no nausea or episodes of emesis; receiving rescue antiemetic during the entire 48 hours' observation **Trial registry number:** NA
Notes	None

Risk of bias

Bias	**Authors' judgement**	**Support for judgement**
Random sequence generation (selection bias)	Low risk	Quote: "computer-generated random number concealed in an opaque envelope"
Allocation concealment (selection bias)	Unclear risk	Quote: "concealed in an opaque envelope" Judgement comment: not stated; "sequentially numbered, opaque, and sealed envelope (SNOSE)"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "study drugs, up to 10 ml with normal saline, were prepared by an anesthesiologist independent of the study and were injected IV over 30 s"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "patient interviews were conducted in a standardized fashion by trained nurses who were blinded to the study drug"

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Chan 2006 *(Continued)*

Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "among 518 eligible patients, 400 were enrolled into the study. Six patients were withdrawn after randomization because of cancellation of surgery (three in the control group; two in the droperidol group and one in the ondansetron and droperidol group). None of these patients received the assigned study drug. Therefore, the final dataset consisted of 394 patients (Fig. 1). One patient in the control group mistakenly received metoclopramide before the end of surgery. This patient was included in the allocated group for all analyses"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Low risk	Quote: "at baseline, patient characteristics and operative details were similar among groups (Table 1). Overall, 285 patients (72%) reported three or more of the common risk factors for PONV, namely female gender, history of PONV or motion sickness, nonsmoker or use of postoperative opioids. The incidence of risk factors was evenly distributed among groups" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Chaparro 2010 *(Continued)*

- *Enrolled (n)*: -
- *Randomized (n)*: 80
- *Received treatment (n)*: 80
- *Analysed (n)*: 80
- *Age (mean ± SD, median (IQR), median (range))*: 30.1 ± 7.5
- *Weight (mean ± SD, median (IQR), median (range))*: 55.9 ± 7.1
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA/NA/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: 100
- *History of PONV/motion sickness (%)*: 21.5/40
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 142.3
- *Use of perioperative opioids (if yes, which?)*: intraoperative morphine 0.05 mg/kg, 3.28 mg postoperative morphine consumption
- *Type of surgery*: plastic or ENT surgery

Included criteria: non-smoking women, between 18 and 50 years of age, ASA I or II, scheduled for ambulatory surgery (plastic and otorhinolaryngologic procedures), under general anaesthesia

Excluded criteria: allergies to metoclopramide, non-steroidal anti-inflammatory drugs (NSAIDs), morphine, or haloperidol; history of extrapyramidal syndrome or akathisia; had used antiemetics within 24 hours preceding surgery or steroids anytime during the previous 3 months

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Interventions	**Intervention characteristics** Dexamethasone • *Dose*: 8 mg • *Time point of administration*: 30 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 18.75% (metoclopramide 10 mg) Dexamethasone + haloperidol • *Dose*: dexamethasone 8 mg, haloperidol 1.5 mg • *Time point of administration*: 30 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 15% (metoclopramide 10 mg)
Outcomes	*Vomiting (0 to 24 hours)* • Outcome type: dichotomous outcome *Vomiting (2 to 6 hours)* • Outcome type: dichotomous outcome *Nausea (0 to 24 hours)* • Outcome type: dichotomous outcome *Extrapyramidal symptoms (0 to 24 hours)* • Outcome type: dichotomous outcome *Sedation/drowsiness (0.5 hours, 0.5 to 2 hours, 2 to 6 hours)*

Chaparro **Institution:** Toronto Western Hospital, Canada **Email:** luisdr74@yahoo.com **Address:** Toronto Western Hospital, Comprehensive Pain Program, Rm 811-4 Fell Pavilion, 399 Bathurst Street, Toronto, ON M5T 2S8, Canada **Duration of study:** April to December 2005 **Language:** English **Study's primary outcome:** postoperative nausea and vomiting **Trial registry number:** NA
Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "which randomized these two treatment groups according to a computer-generated list using"
Allocation concealment (selection bias)	Low risk	Quote: "at study onset, the hospital pharmacist prepared a concealed treatment allocation schedule" Judgement comment: central allocation
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "staff members involved in patient care were blinded to the patients' assignment"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "[8]. All data were collected by an anaesthesiologist (L.E.C.) or resident (N.J.G., M.F.R., and T.G.) who [was] blinded to the patient group assignment"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "a total of 192 consecutive patients were screened (Fig. 1). Twenty-two did not meet inclusion criteria, seven did not accept to participate and three preferred a 5-HT3 antagonist as antiemetic. One hundred and sixty nonsmoker women were recruited and randomized" Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Chaparro 2010 *(Continued)*

Other bias	Low risk	Quote: "there were no differences in the various demographic variables between the two groups" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Judgement comment: quote: "allocated randomly to receive either ondasetron 4 mg or metoclopramide 10 mg using a series of sealed envelopes" Insufficient information on the sequence generation process
Allocation concealment (selection bias)	Unclear risk	Judgement comment: quote: "allocated randomly to receive either ondasetron 4 mg or metoclopramide 10 mg using a series of sealed envelopes" Detailed information on envelopes is missing (SNOSE)
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Judgement comment: quote: "double-blinded" Insufficient information on blinding
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Judgement comment: quote: "sedation, nausea and vomiting were assessed by an investigator blinded to the study drug"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: quote: "twenty-five patients were initially recruited into each Group. One Patient in the metoclopramide group was excluded after she developed post-operative respiratory depression" Reasons for missing data from 1 patient were described and are unlikely related to outcomes of interest
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness, perioperative opioids): no; (non-smoker): unclear

- *Use of perioperative opioids (if yes, which?)*: 167 µg fentanyl, meperidine consumption at 0 to 12 hours of 21.2 mg and at 12 to 24 hours of 12.4 mg
- *Type of surgery*: otolaryngological, orthopaedic, ophthalmological, laparoscopic, laparotomy, other

Dexamethasone (group D)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 350
- *Received treatment (n)*: 350
- *Analysed (n)*: 350
- *Age (mean ± SD, median (IQR), median (range))*: 52 ± 15
- *Weight (mean ± SD, median (IQR), median (range))*: 61.7 ± 6.7
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: NA/NA/0/0
- *Gender (female in %)*: 60
- *Non-smoker (%)*: 74
- *History of PONV/motion sickness (%)*: 37
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 163
- *Use of perioperative opioids (if yes, which?)*: 177 µg fentanyl, meperidine consumption at 0 to 12 hours of 22.3 mg and at 12 to 24 hours of 11.7 mg
- *Type of surgery*: otolaryngological, orthopaedic, ophthalmological, laparoscopic, laparotomy, other

Included criteria: ASA I or II, surgical patients about to undergo surgery under general anaesthesia

Excluded criteria: significant medical disease; had received antiemetics within 24 hours before surgery; history of immunosuppression, significant oesophageal-gastric reflux, Cushing's syndrome, or liver/renal disease; presented difficult intubation during induction of anaesthesia

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Interventions

Intervention characteristics

Placebo (group P)

- *Dose*: saline
- *Time point of administration*: 1 minute before induction of anaesthesia
- *Route of administration*: IV

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "the randomization was achieved using the envelope method (700 envelopes, 350 stated as control group and 350 stated as study group were polled together. The researcher picked one of these envelopes after the patient agreed to enroll into the study)"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: not stated: "sequentially numbered, opaque, sealed envelopes (SNOSE)"
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Quote: "double-blinded" Judgement comment: insufficient information on blinding ("double-blinded")
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding ("double-blinded")
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "data obtained from the 700 patients (350 in each group) were analyzed" Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Low risk	Quote: "the incidence of background factors and factors related to operation and anesthesia, which may modify PONV, did not differ between the two groups (Table 1)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Notes	Two out of 4 groups relevant (vitamin B1 acupuncture point injection)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "simple randomisation, using computer-generated random numbers"
Allocation concealment (selection bias)	Unclear risk	Quote: "concealed until the patient entered the postanaesthesia care unit" Judgement comment: no details on allocation concealment provided
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "...injection[s] were also recorded carefully. Patients, anaesthetists, surgical, nursing staff and our follow-up investigators were all blinded to the group allocation. The investigator [was] responsible for collecting"

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Chen 2014 *(Continued)*

Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "by an observer who was blinded to the research design" Quote: "the investigator responsible for collecting data was also unaware of the treatments assigned"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "(Figure 2)"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Low risk	Quote: "demographic characteristics, the risk score for POV and all the perioperative variables in the four groups were not significantly different (table 1)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, perioperative opioids): no; (history of PONV/motion sickness, non-smoker): unclear (data not shown, but no difference in risk scores between groups)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "patients were randomly and equally divided into three groups, using a computer-generated table of random numbers"

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Chia 2004 *(Continued)*

Allocation concealment (selection bias)	Low risk	Quote: "the pharmacy personnel who were not involved in patient care or evaluation was allowed to undertake group-assignment and randomization, which was achieved using a sequence of random numbers from a computer-generated sequence. The group-assignment code indicating group assign was retained by the pharmacy until the conclusion of the study. To ensure patient safety, however, a sealed opaque envelope containing the randomized treatment assignment was kept with the patient in the operating room and intensive care unit (ICU) to permit immediate unmasking if necessary"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "double blinding was achieved by having our hospital pharmacy personnel prepare the infusion bags with promethazine or not for each group of patients and label them with the subject's identification number only" Quote: "an anaesthesiologist, blinded to group membership and not involved in postoperative evaluation or patient contact, conducted the anaesthesia"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "an anaesthesiologist blinded to group allocation evaluated the patients when they were sufficiently awake and alert post surgery, and recorded the data"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "a total of 102 patients were evaluated. Of these, six were excluded due to surgical complications such as massive perioperative bleeding and wound infection. In addition, six patients did not complete the experiment due to transfer for chemotherapy or addition of non-steroidal anti-inflammatory drugs to their treatment regimen for pain management. This left a sample population of 90 patients in the three groups"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia): no; (history of PONV/motion sickness, non-smoker): unclear; (perioperative opioids): yes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "assigned by use of a computer generated random number table into one of five groups"
Allocation concealment (selection bias)	Low risk	Judgement comment: no statement

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Chu 2008 *(Continued)*

Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Quote: "study medications were prepared by a nurse anesthetist in identical syringes with a total volume of 2 ml (dilution with saline), and given IV 15 min after the induction of anesthesia. Patients and the investigators who collected the postoperative data were blinded to the randomization" Judgement comment: no information on blinding of anaesthesiologist
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "patients and the investigators who collected the postoperative data were blinded to the randomization"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "twenty-eight of the 400 patients enrolled in the study were excluded from the analysis; 16 patients required an abdominal hysterectomy, and, in 12 patients, we were unable to collect complete data. The data obtained from the remaining 372 patients were analyzed"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "patient characteristics such as age, weight, height, histories of PONV and motion sickness, and durations of surgery and anesthesia were not different among the five groups" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness, perioperative opioids): no; (non-smoker): unclear

Cortes Flores 2018 *(Continued)*

- *Duration of anaesthesia or surgery (in min; as mean or median)*: 82.8
- *Use of perioperative opioids (if yes, which?)*: fentanyl 1 µg/kg (premedication) + 3 µg/kg (induction), 2.5 mg morphine for postoperative pain
- *Type of surgery*: partial mastectomy

Included criteria: women scheduled to receive an elective partial mastectomy with or without axillary gland removal, confirmed diagnosis of breast carcinoma

Excluded criteria: ASA III or IV disease; over 70 years of age; pregnancy; previous steroid therapy; uncontrolled diabetes mellitus (serum glycated haemoglobin level > 8%); use of opioids, sedatives, or analgesics within a week before surgery; any history of alcohol or drug abuse, inner ear disease, and/or uncontrollable severe PONV after any surgical procedure

Pretreatment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker): no; (history of PONV/motion sickness): unclear; (perioperative opioids): yes

Interventions	**Intervention characteristics** Dexamethasone + ondansetron • *Dose*: dexamethasone 8 mg, ondansetron 4 mg • *Time point of administration*: dexamethasone 1 hour before surgery, ondansetron during surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: ondansetron 4 mg IV Ondansetron • *Dose*: 4 mg • *Time point of administration*: placebo 1 hour before surgery, ondansetron during surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: ondansetron 4 mg IV
Outcomes	*Vomiting (6 to 12 hours)* • Outcome type: dichotomous outcome *Mortality (during study, 24 hours)* • Outcome type: dichotomous outcome *Postoperative wound infection (during study, 24 hours)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 24 hours' observation)* • Outcome type: general notes on side effects
Identification	**Sponsorship source:** NA **Country:** Mexico **Setting:** inpatient, single-centre **Author's name:** Alejandro González-Ojeda **Institution:** Biomedical Research Unit 02, Specialities Hospital of the Western National Medical Center,Mexican Institute of Social Security, Guadalajara, Mexico **Email:** avygail5@yahoo.com.mx ; avygail5@gmail.com

Address: Biomedical Research Unit 02, Specialties Hospital of the Western Medical Center, Mexican Institute of Social Security, Guadalajara, Mexico

Duration of study: June 2013 to October 2014

Language: English

Study's primary outcome: NA

Trial registry number: NCT02305173

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "patients were randomly allocated by sealed envelope assignment"
Allocation concealment (selection bias)	Unclear risk	Quote: "sealed envelope assignment" Judgement comment: not stated; "sequentially numbered, opaque, sealed envelopes" (SNOSE)
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding ("double-blind")
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding ("double-blind")
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: NCT02305173 (retrospective registration)
Other bias	High risk	Quote: "the selection of patients is described in Figure 1. Age and anthropometric measures did not differ significantly between groups (Table 1). The most frequent comorbid conditions observed were type 2 diabetes and hypertension. Tobacco was used by 23% of patients in the treatment group and 20% in the control group. The anaesthesia and mask removal times and details about intraoperative blood loss for both groups are shown in Table 1. These variables did not differ significantly between the two groups. Analysis of the post operative..." Quote: "the frequency of use of morphine was significantly different between groups at 1 (p = .01), 6 (p = .02), and 12 (p = .04) hr" Judgement comment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker): no; (history of PONV/motion sickness): unclear; (perioperative opioids): yes

Cubukcu 2007 *(Continued)*

- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 10/20/0/0
- *Gender (female in %)*: 72
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 0
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 160.0
- *Use of perioperative opioids (if yes, which?)*: morphine 34.9 mg via PCA
- *Type of surgery*: lower extremity surgery

Ondansetron (morphine group)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: NA
- *Received treatment (n)*: NA
- *Analysed (n)*: 25
- *Age (mean ± SD, median (IQR), median (range))*: 44.9 ± 18.6
- *Weight (mean ± SD, median (IQR), median (range))*: 68.5 ± 14.0
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 13/17/0/0
- *Gender (female in %)*: 50
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: 0
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 160.4
- *Use of perioperative opioids (if yes, which?)*: morphine 35.4 mg via PCA
- *Type of surgery*: lower extremity surgery

Included criteria: ASA I or II, elective lower extremity surgery

Excluded criteria: severe CHD; renal or liver disease; motion sickness; history of PONV; over 18 years of age; lack of understanding in using PCA pump; allergy to morphine, ondansetron, or tramadol

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, history of PONV/motion sickness, duration of anaesthesia): no; (non-smoker): unclear; (perioperative opioids): yes

Interventions	**Intervention characteristics** Placebo (tramadol group) • *Dose*: saline • *Time point of administration*: at induction of anaesthesia • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: NA Ondansetron (tramadol group) • *Dose*: 0.1 mg/kg • *Time point of administration*: at induction of anaesthesia • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: NA Placebo (morphine group) • *Dose*: saline

Notes	Two out of 3 groups relevant (ephedrine group not relevant)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "randomized into three groups" Judgement comment: no further information on sequence generation provided
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "these drugs were prepared and given ten minutes before the end of the procedure by a single anesthetist who took no part in data collection"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "for severe nausea or vomiting by trained nurse without knowledge of which drugs the patients had received. Emesis score < 2..."
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "patient characteristics such as age, weight, duration of anesthesia and surgery, recovery time, and intraoperative fluid requirement were comparable in the 3 groups (Table 1)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (duration of anaesthesia, non-smoker, perioperative opioids): no; (gender, history of PONV/motion sickness): unclear

Notes	Four groups pooled into 2 groups with same interventions for analysis

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "a random number was used to assign prospectively each patient to receive after induction of anesthesia either ondansetron 4 mg (A), or metoclopramide 10 mg (B)"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the staff caring for these patients were blinded to the study drug received"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "an independent blinded observer recorded emetic episodes" Quote: "after two hours, patients were discharged to the floor, where they were followed up to 24 hours by another independent observer; the number of patients who vomited was recorded in each group" Quote: "the staff caring for these patients were blinded to the study drug received"

- *Type of surgery*: laparoscopic cholecystectomy or herniorrhaphy

Included criteria: ASA I or II, scheduled for laparoscopic cholecystectomy or herniorrhaphy

Excluded criteria: known allergies or hypersensitivity to study drugs, history of chronic nausea and vomiting or experienced nausea and vomiting in the past 24 hours before anaesthesia, had received any antiemetics or any drug with antiemetic properties during the 24 hours before anaesthesia, BMI ≥ 35 kg/m^2, over 70 years of age, pregnant or breastfeeding, had a condition requiring long-term opioid use

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness): no; (perioperative opioids): unclear

Interventions	**Intervention characteristics** Granisetron + dexamethasone • *Dose*: granisetron 1 mg, dexamethasone 8 mg • *Time point of administration*: immediately after induction of anaesthesia • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: metoclopramide 10 mg IV Ondansetron + dexamethasone • *Dose*: ondansetron 4 mg, dexamethasone 8 mg • *Time point of administration*: immediately after induction of anaesthesia • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: metoclopramide 10 mg IV
Outcomes	*Vomiting (6 to 24 hours)* • Outcome type: dichotomous outcome *Headache (PACU)* • Outcome type: dichotomous outcome *Sedation/drowsiness (PACU)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 24 hours' observation)* • Outcome type: general notes on side effects

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "using a computer generated randomization method"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "were presented to blinded investigators as identical 2 ml filled syringes" Quote: "the study medications were prepared by a resident, who was not involved in any other part of the study, and were presented to blinded investigators..."
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "adverse events were evaluated and recorded by a resident who was blinded to the study drugs used"
Incomplete outcome data (attrition bias) All outcomes	High risk	Quote: "of the 100 patients initially signing the informed consent, 84 patients (42 in group I, 42 in group II) completed the study" Judgement comment: missing data > 15%. No reasons mentioned for loss of participants
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "there was no statistically significant difference between the two groups in regards to gender, history of PONV and history of motion sickness, age, weight, type of surgery (laparoscopic cholecystectomy or laparoscopic herniorraphy), duration of surgery, history of prolonged gastric emptying, and smoking history (Table 1)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness): no; (perioperative opioids): unclear

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "excluded. Randomization was based on a computer-generated code"
Allocation concealment (selection bias)	Low risk	Quote: "prepared at a remote site and sealed in sequentially numbered, opaque envelopes"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the investigators involved [in] the operation and the postoperative care (P.W., M.M.H., and J.H.-L) were blinded regarding the content of the study medication"
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Judgement comment: no statement on blinding of outcome assessors
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "60 female patients were enrolled in our study, 30 for each group. The data of all patients were eligible for statistical analyses. The H-Group and the H/O-Group were comparable regarding demographic data (table 1). All patients completed the study protocol"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, history of PONV/motion sickness, non-smoker): no; (duration of anaesthesia, perioperative opioids): unclear

- *Use of perioperative opioids (if yes, which?)*: fentanyl 2 µg/kg to 10 µg/kg, morphine 1 mg to 4 mg as rescue analgesic
- *Type of surgery*: open abdominal hysterectomy

Included criteria: female patients 18 to 64 years of age were eligible for enrolment if they were scheduled to undergo elective open abdominal hysterectomy requiring general anaesthesia and had ASA status of I to III. Concomitant procedures were limited to salpingectomy, oophorectomy, and lysis of adhesions

Excluded criteria: scheduled to receive propofol for induction and/or maintenance of anaesthesia; had known hypersensitivity to granisetron, or any agent that was part of the anaesthesia regimen, or other medications to be administered relative to surgery; were pregnant or breastfeeding; had experienced retching/vomiting or moderate or severe nausea in the 24 hours before anaesthesia; had chronic nausea and/or vomiting; had received an antiemetic drug or a drug with antiemetic properties within the 24 hours before anaesthesia or were scheduled to receive such medications during surgery or within the 24 hours following surgery; had body mass index ≥ 34; had a condition that required long-term opioid use

Pretreatment: baseline characteristics (age, weight): no; (ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia): no; (perioperative opioids): unclear; (non-smoker, history of PONV/motion sickness): yes

Interventions	**Intervention characteristics** Granisetron (0.1 mg group) • *Dose*: 0.1 mg • *Time point of administration*: 15 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 55% (discretion of the investigator) Granisetron (0.3 mg group) • *Dose*: 0.2 mg • *Time point of administration*: 15 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 68% (discretion of the investigator) Granisetron (0.3 mg group) • *Dose*: 0.3 mg • *Time point of administration*: 15 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 43% (discretion of the investigator) Placebo • *Dose*: saline 0.9% • *Time point of administration*: 15 minutes before end of surgery

Identification	**Sponsorship source:** this research was supported by Roche Laboratories Inc., Nutley, New Jersey **Country:** USA **Setting:** inpatient, multi-centre (11) **Author's name:** Robert D'Angelo **Institution:** Wake Forest University School of Medicine, Winston-Salem, NC, USA **Email:** rdangelo@wfubmc.edu **Address:** Wake Forest University School of Medicine, Forsyth Medical Center, 333 Silas Street Parkway, Winston-Salem, NC 27013, USA **Language:** English **Duration of study:** 12 March to 16 August 2002 **Trial registry number:** NA **Study's primary outcome:** no vomiting in 0 to 6 hours
Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "treatment assignment was based on computer-generated randomization lists prepared by the study sponsor prior to the study. Separate randomization lists were generated for each study site using a prespecified block size"
Allocation concealment (selection bias)	Low risk	Quote: "patient randomization numbers were assigned sequentially at each site in the order in which patients were enrolled. The randomization list at each site was provided only to the unblinded pharmacist who prepared the injection. The pharmacist was not involved in any other part of the study. To

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

DAngelo 2005 *(Continued)*

		maintain blinding, study medications were presented by the pharmacist to the investigator as identical 5 ml solutions for injection in 10 ml syringes" Judgement comment: allocation was adequately concealed
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "in which patients were enrolled. The randomization list at each site was provided only to the unblinded pharmacist who prepared the injection. The pharmacist was not involved in any other part of the study. To maintain blinding, study medications were presented by the pharmacist to the investigator as identical 5 ml solutions for injection in 10 ml syringes. On the day of the scheduled surgery, a baseline physical examination..."
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Judgement comment: it is clear from the description of the the domains "sequence generation", "allocation concealment", and "blinding of participants and personnel" whether the only person who knew the group allocation was the unblinded pharmacist, who was not involved in any other part of the study. Therefore, all other study staff had to be blind to group allocation
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "in all, 140 patients scheduled for abdominal hysterectomy were enrolled in the study between 12 March and 16 August 2002 at 11 study centres in the USA. Of these, 121 patients were randomized, treated with study medication and included in efficacy and safety analyses. One patient in the granisetron 0.1 mg treatment group was withdrawn from the study prematurely due to additional surgery requiring repeat anaesthesia approximately 2 hours after the original surgery was completed" Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Quote: "patient characteristics and other baseline characteristics are summarized in Table 1. For some variables such as history of motion sickness or smoking, randomization did not result in equal distributions across treatment groups" Judgement comment: baseline characteristics (age, weight): no; (ASA): unclear. Potential effect modifiers (gender, duration of anaesthesia): no; (perioperative opioids): unclear; (non-smoker, history of PONV/motion sickness): yes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "the patients were prospectively randomized" Judgement comment: no further information on sequence generation provided
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	High risk	Judgement comment: no blinding of participants or personnel (different routes of administration, no sham treatment)
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Quote: "the staff evaluating the patients during postoperative period was blinded for postoperative nausea and vomiting" Judgement comment: insufficient information on blinding of outcome assessors
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "two patients in group O (because of missing data), one patient in group DT and one patient in the placebo group discontinued and all were excluded. Data from the remaining 90 patients included in the study were analyzed (30 patients in each group)"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "there were no statistically significant differences between the group members in weight, height, age, bleeding and duration of general anesthesia (Table 2)" Judgement comment: baseline characteristics (age, weight): no; (ASA I to III): unclear. Potential effect modifiers (gender, anaesthesia): no; (non-smoker, history of PONV/motion sickness, use of perioperative opioids): unclear

Notes	Two out of 3 groups relevant (co-administration of pregabalin in both groups)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "computer-generated list of random numbers"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "by the same researcher who was not involved in the intraoperative or postoperative treatment and data collection" Quote: "...P and PD, and a similar-looking placebo capsule was given to the controls (Group C) by the same researcher who was not involved in the intraoperative or postoperative treatment and data collection. The exact same packaging was used for the placebo capsules as the active capsules. In the operating room, intravenous..."
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "the NRS values were recorded at 30 min and 1 h in the PACU and at 2, 4, 8, 12, and 24 h in the inpatient unit by the same researcher who was totally unaware of the patient groups"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Quote: "Group P and Group PD exhibited statistically significant lower tramadol consumption compared to Group C within the 0–24-h postoperative period (p \ 0.01 for all). There was a statistically significant difference between Group P and Group PD with respect to tramadol consumption (p = 0.016) only in the first 1-h period. Table 2 and Fig. 1 give the mean tramadol consumption (mg) of the groups within the first 24-h period" Judgement comment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia): no; (history of PONV/motion sickness, non-smoker): unclear; (perioperative opioids): yes

Setting: outpatient, single-centre

Author's name: R.J. McCarthy

Institution: Department of Anesthesiology, Northwestern University Feinberg School of Medicine, Chicago, USA

Email: r-mccarthy@northwestern.edu

Address: Department of Anesthesiology, Northwestern University Feinberg School of Medicine, 251 E. Huron St., Feinberg 5-704, Chicago, IL 60611, USA

Duration of study: January 2010 to September 2010

Language: English

Study's primary outcome: primary outcome was global QoR-40 at 24 hours

Trial registry number: NCT01052038

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "computer-generated table into three groups"
Allocation concealment (selection bias)	Low risk	Quote: "group assignments were sealed in sequentially numbered opaque envelopes that were opened by a research nurse not involved with the subjects' care"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the anaesthesia care team was blinded to group allocation"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "subjects were contacted 24 h after the procedure by an investigator unaware of group allocation and were asked about analgesic consumption and the QoR-40 questionnaire was administered" Quote: "the anaesthesia care team was blinded to group allocation"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "one hundred and twenty subjects were randomized and 106 completed the study" Judgement comment: reasons for missing outcome data described and unrelated to outcomes of interest
Selective reporting (reporting bias)	High risk	Judgement comment: NCT01052038 (prospective registration). Primary outcome as defined in the protocol was changed in the study report from "sore throat pain" to "QoR-40 aggregate score" (which was one of the secondary outcomes in the protocol). Primary outcome was not PONV-related
Other bias	High risk	Quote: "patient's baseline characteristics and surgical factors were not different among groups (Table 2)" Judgement comment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia): no; (history of PONV/motion sickness, non-smoker): unclear; (perioperative opioids): yes

DeOliveira 2016 *(Continued)*

- *Received treatment (n)*: 30
- *Analysed (n)*: 24
- *Age (mean ± SD, median (IQR), median (range))*: 37 (33.5 to 43)
- *Weight (mean ± SD, median (IQR), median (range))*: NA
- *BMI (mean ± SD, median (IQR), median (range))*: 26.3 ± 4.8
- *ASA I/II/III/IV (n)*: 10/14/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: NA
- *History of PONV/motion sickness (%)*: NA
- *Type of general anaesthesia*: balanced anaesthesia (sevoflurane, remifentanil)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 105
- *Use of perioperative opioids (if yes, which?)*: 528 µg intraoperative remifentanil, postoperative hydromorphone orally
- *Type of surgery*: gynaecological laparoscopy

Included criteria: healthy women undergoing outpatient gynaecological laparoscopy

Excluded criteria: history of allergy to diphenhydramine, long-term use of an opioid analgesic or corticosteroid, pregnant subjects, conversion from a laparoscopic to an open incision

Pretreatment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, perioperative opioids): no; (history of PONV/motion sickness, non-smoker): unclear

Interventions	**Intervention characteristics** Ondansetron • *Dose*: 4 mg • *Time point of administration*: saline after anaesthesia induction, ondansetron at end of procedure • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: metoclopramide 10 mg IV, prochlorperazine 5 mg IV Diphenhydramine (25 mg group) + ondansetron • *Dose*: diphenhydramine 25 mg, ondansetron 4 mg • *Time point of administration*: diphenhydramine after anaesthesia induction, ondansetron at end of procedure • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: metoclopramide 10 mg IV, prochlorperazine 5 mg IV Diphenhydramine (50 mg group) + ondansetron • *Dose*: diphenhydramine 50 mg, ondansetron 4 mg • *Time point of administration*: diphenhydramine after anaesthesia induction, ondansetron at end of procedure • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: metoclopramide 10 mg IV, prochlorperazine 5 mg IV
Outcomes	*Vomiting (PACU)* • Outcome type: dichotomous outcome
Identification	**Sponsorship source:** Department of Anesthesiology, Northwestern University **Country:** USA **Setting:** outpatient, single-centre **Author's name:** Gildasio S. De Oliveira

Study's primary outcome: Global Quality of Recovery–40 score at 24 hours

Trial registry number: NCT01451762

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "using a computer-generated table of random numbers"
Allocation concealment (selection bias)	Low risk	Quote: "group assignments were sealed in sequentially numbered, opaque envelopes that were opened by a research nurse not involved with patient care or data collection after the subject provided written informed consent"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "subject provided written informed consent. The same nurse prepared syringes labeled with study drug to blind the anesthesia personnel and the investigators collecting..."
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "subject provided written informed consent. The same nurse prepared syringes labeled with study drug to blind the anesthesia personnel and the investigators collecting the data. All subjects were premedicated..."
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Quote: "the details of the conduct of the study are shown in Fig. 1. Ninety subjects were randomized, and 75 completed the study. Patients were enrolled consecutively from September 2011 through September 2012" Judgement comment: number of dropouts > 15%. Reasons described
Selective reporting (reporting bias)	Unclear risk	Judgement comment: NCT01451762 (retrospective registration)
Other bias	Unclear risk	Quote: "patient's baseline characteristics and surgical factors were not different between groups (Table 1)" Judgement comment: baseline characteristics (age, BMI, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, perioperative opioids): no; (history of PONV/motion sickness, non-smoker): unclear

Dewinter 2016 *(Continued)*

- *Non-smoker (%)*: 75.9
- *History of PONV/motion sickness (%)*: 18.1/NA
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 95
- *Use of perioperative opioids (if yes, which?)*: 0.3 µg/kg sufentanil
- *Type of surgery*: laparoscopic gynaecological surgery

Placebo

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 123
- *Received treatment (n)*: 123
- *Analysed (n)*: 123
- *Age (mean ± SD, median (IQR), median (range))*: 39 (31 to 51)
- *Weight (mean ± SD, median (IQR), median (range))*: 65 (57 to 73)
- *BMI (mean ± SD, median (IQR), median (range))*: 23 (21 to 26)
- *ASA I/II/III/IV (n)*: NA/NA/0/0
- *Gender (female in %)*: 100
- *Non-smoker (%)*: 71
- *History of PONV/motion sickness (%)*: 19/NA
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 110
- *Use of perioperative opioids (if yes, which?)*: 0.3 µg/kg sufentanil
- *Type of surgery*: laparoscopic gynaecological surgery

Included criteria: ASA I or II, women older than 18 years of age, scheduled for laparoscopic gynaecological surgery

Excluded criteria: hypersensitivity to any of the study medications, ASA III to V, pregnancy, parkinsonism, mental disorders, psychiatric illness, consumption of antiemetic drugs within 24 hours before initiation of the study

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV, perioperative opioids): no; (history of motion sickness): unclear

---

Interventions

Intervention characteristics

Ondansetron

- *Dose*: 4 mg
- *Time point of administration*: approximately 30 minutes before end of surgery
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: first-line droperidol 1.25 mg and dexamethasone 5 mg IV; second-line ondansetron 4 mg and alizapride 100 mg IV

Alizapride

- *Dose*: 100 mg
- *Time point of administration*: approximately 30 minutes before end of surgery
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: first-line droperidol 1.25 mg and dexamethasone 5 mg IV; second-line ondansetron 4 mg and alizapride 100 mg IV

Placebo

- *Dose*: saline

- *Time point of administration*: approximately 30 minutes before end of surgery
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: first-line droperidol 1.25 mg and dexamethasone 5 mg IV; second-line ondansetron 4 mg and alizapride 100 mg IV

Outcomes	*Vomiting (PACU)* • Outcome type: dichotomous outcome *PONV (0 to 24 hours)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 24 hours' observation)* • Outcome type: general notes on side effects
Identification	**Sponsorship source:** none **Country:** Belgium **Setting:** inpatient and outpatient, single-centre **Author's name:** Geertrui Dewinter **Institution:** Department of Anesthesiology, University Hospitals of the KU Leuven, Leuven, Belgium (SF) **Email:** geertrui.dewinter@uzleuven.be **Address:** Herestraat 49, Leuven 3000, Belgium **Duration of study:** November 2008 to July 2011 **Language:** English **Study's primary outcome:** incidences of PON (VAS score ≥ 1) and POV in PACU **Trial registry number:** EUCTR2008-004789-20
Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "randomisation was performed using a computer-generated randomisation code (Microsoft Excel)"
Allocation concealment (selection bias)	Low risk	Quote: "allocation concealment was ensured by enclosing assignments in sealed, opaque, sequentially numbered envelopes that were opened only after arrival of the patient in the operation room"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "patients, anaesthetists and the study nurse who collected the trial data were blinded to group allocation"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "patients, anaesthetists and the study nurse who collected the trial data were blinded to group allocation"

Dewinter 2016 *(Continued)*

Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: reasons for exclusions were described and were unrelated to outcomes of interest
Selective reporting (reporting bias)	Unclear risk	Judgement comment: EUCTR2008-004789-20 (prospective registration). Timing of assessment of the primary outcome (PONV) was not defined in the protocol
Other bias	Unclear risk	Quote: "patients did not differ in respect of demographic/biometric data, risk factors for PONV, or durations of anaesthesia and surgery (Table 1). All patients received opioids perioperatively with no difference in opioid doses among the three groups" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV, perioperative opioids): no; (history of motion sickness): unclear

- *Rescue antiemetics (if yes, which?)*: e.g. metoclopramide, cyclizine

Dolasetron (25 mg group)

- *Dose*: 25 mg
- *Time point of administration*: at end of N_2O administration
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: e.g. metoclopramide, cyclizine

Dolasetron (50 mg group)

- *Dose*: 50 mg
- *Time point of administration*: at end of N_2O administration
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: e.g. metoclopramide, cyclizine

Dolasetron (100 mg group)

- *Dose*: 100 mg
- *Time point of administration*: at end of N_2O administration
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: e.g. metoclopramide, cyclizine

Outcomes	*Complete response (no PONV) in 24 hours* • Outcome type: dichotomous outcome *Subjects with any SAE (0 to 24 hours)* • Outcome type: dichotomous outcome *Headache (0 to 24 hours)* • Outcome type: dichotomous outcome *Sedation/drowsiness (0 to 24 hours)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 24 hours' observation)* • Outcome type: general notes on side effects

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "followed cessation of N,O. Patients were stratified and randomly assigned via sealed envelope assignment from..." Judgement comment: no further information on sequence generation provided
Allocation concealment (selection bias)	Unclear risk	Quote: "...via sealed envelope assignment" Judgement comment: not stated; "sequentially numbered, opaque, sealed envelopes" (SNOSE)
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Quote: "...or 100 mg dolasetron mesilate. Ampules containing 10 ml of placebo (sterile saline) or dolasetron mesilate in concentrations of 2.5 mg/ml, 5 mg/ml, 10 mg/ml, or 20 mg/ml were provided by Hoechst Marion Roussel, Inc. To achieve the required dose for each patient, 5 ml of solution was withdrawn from the appropriate ampule, diluted to 50 ml with sterile saline for injection, and administered IV..." Judgement comment: no detailed information on blinding of anaesthesiologists; syringes not stated identical; not clear who is preparing the study drugs
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Judgement comment: insufficient information on blinding ("double-blind")
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Quote: "study at 10 investigative sites. There were no statistically significant differences among the five treatment groups with respect to age, weight, height, ASA physical status, and posttreatment administration of morphine (Table I). The difference in the proportion of patients with and without a history of PONV approached statistical significance ($I = 0.053); the 50 mg dolasetron mesilate treatment group had the lowest percentage of patients with a history of PONV (15%), and the placebo group had the highest percentage (36%). As shown in Table 2" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender): no; (history of motion sickness, duration of anaesthesia, non-smoker): unclear; (history of PONV, perioperative opioids): yes

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "randomized" Judgement comment: no further information on sequence generation provided
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Quote: "because dolasetron tablets vary in size according to dose, each patient received a total of four tablets: one containing either 25, 50, 100, or 200 mg dolasetron, plus three placebo tablets identical to the other sizes, or four placebo tablets" Judgement comment: insufficient information on blinding of anaesthesiologists
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Judgement comment: no statement
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "of the 793 patients enrolled in the study, four did not undergo surgery (for reasons unrelated to study drug) and were excluded from the intent-to-treat efficacy data set"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Diemunsch 1998 *(Continued)*

Other bias	Unclear risk	Quote: "baseline characteristics were well balanced among treatment groups (Table 1). The study population was predominately Caucasian (96%) and of ASA physical status I (75%). Patients' mean age was 43 years, mean weight was 68 kg, and mean height was 163 cm. History of PONV was reported in 32% and history of motion sickness in 18% of patients. There were no statistically significant imbalances among treatment groups in duration of anesthesia. Additionally, there were no statistically significant imbalances among treatment groups in use of concomitant medications, use of postoperative opioids or NSAIDs, or in type or dose of medications used for premedication, induction, maintenance, and reversal of anesthesia" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV/motion sickness, perioperative opioids): no; (non-smoker): unclear

Diemunsch 2007 *(Continued)*

Duration of study: 28 May 2004 to 20 April 2005

Language: English

Study's primary outcome: primary endpoints for the efficacy analysis were (1) complete response (no vomiting and no use of rescue therapy) over 0 to 24 hours after surgery, to be analysed first for non-inferiority of aprepitant, followed by superiority of aprepitant if non-inferiority was demonstrated, and (2) no vomiting over 0 to 24 hours after surgery, to be tested for superiority of aprepitant

Trial registry number: NCT00090246

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "the gender-stratified randomization schedule was computer-generated by the sponsor"
Allocation concealment (selection bias)	Low risk	Quote: "the sponsor provided supplies of aprepitant, placebo matching aprepitant, and blinded allocation schedules" Quote: "each site designated an unblinded pharmacist otherwise not involved with the study to receive, store, and prepare the ondansetron and saline placebo" Quote: "in order to ensure in-house blinding, the schedule was created by an assistant statistician who was otherwise not involved with the study"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "patient and investigator blinding was maintained with matching placebos"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "...investigator. In addition, to detect possible drug interactions, serious AEs of excessive sedation and respiratory depression were adjudicated in blinded fashion by two physicians not involved with the study"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "among 1004 patients screened, a total of 922 patients were randomized. Of these, 30 patients were excluded from the tolerability and efficacy analyses because they either did not receive any study drug (n 25) or received partial study drug that was found after unblinding to have been the inactive (placebo) portion of the regimen (n 5). In addition to these 30 patients, 26 other patients were excluded from the efficacy analyses for various reasons, as shown in the figure. Reasons for discontinuation were similar among treatment groups"
Selective reporting (reporting bias)	Unclear risk	Judgement comment: NCT00090246 (retrospective registration)
Other bias	Unclear risk	Judgement comment: baseline characteristics (age, ASA): no; (weight): unclear. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "the order of assignment of the drugs followed a random number code"
Allocation concealment (selection bias)	Unclear risk	Quote: "the order of assignment of the drugs followed a random number code. The identity of the substance was not known to the anaesthetist, who merely recorded the code number of the drug on his anaesthetic record after he administered the material" Judgement comment: no details on allocation provided
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the identity of the substance was not known to the anaesthetist"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "the patient's chart was reviewed 24 hours postoperatively to record the incidence of nausea and vomiting and related information. The identity of the compounds administered was not revealed to the principals involved in the study until the study was completed and all the data were tabulated"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "each patient's record was reviewed 24 hours after the operation to obtain follow-up data" Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported

Duration of study: NA

Trial registry number: NA

Study's primary outcome: NA

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "generated random number list to assign patients into three equal groups (n=20)"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Quote: "anaesthetists were blinded to the group to which the patients had been assigned" Judgement comment: no statement on blinding of participants
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Quote: "postoperatively, all episodes of PONV were recorded for the first 24 hours (0-2, 2-6, 6-24 hours) by direct questioning by the attending anaesthetist or by spontaneous complaint by the patients" Judgement comment: no statement on blinding of outcome assessors
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, history of PONV, perioperative opioids): no; (history of motion sickness, non-smoker): unclear

Ondansetron

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 50
- *Received treatment (n)*: NA
- *Analysed (n)*: 50
- *Age (mean ± SD, median (IQR), median (range))*: 34.26 ± 13.77
- *Weight (mean ± SD, median (IQR), median (range))*: 60.22 ±- 6.876
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 36/14
- *Gender (female in %)*: 48
- *Non-smoker (%)*: 100
- *History of PONV/motion sickness (%)*: 0/0
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 179.44
- *Use of perioperative opioids (if yes, which?)*: 121.3
- *Type of surgery*: tympanoplasty and mastoidectomy

Granisetron

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 50
- *Received treatment (n)*: NA
- *Analysed (n)*: 50
- *Age (mean ± SD, median (IQR), median (range))*: 32.48 ± 14.56
- *Weight (mean ± SD, median (IQR), median (range))*: 60.66 ± 7.847
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 39/11
- *Gender (female in %)*: 38
- *Non-smoker (%)*: 100
- *History of PONV/motion sickness (%)*: 0/0
- *Type of general anaesthesia*: inhalational anaesthesia (sevoflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 179.5
- *Use of perioperative opioids (if yes, which?)*: 109.8 µg intraoperative fentanyl
- *Type of surgery*: tympanoplasty and mastoidectomy

Included criteria: ASA I or II, 18 to 65 years of age, undergoing middle ear surgery (tympanoplasty and mastoidectomy) under general anaesthesia

Excluded criteria: history of smoking, gastritis, heartburn, motion sickness; previous PONV; lower oesophageal sphincter disorders; Ellison-Zollinger syndrome; uncontrolled hypertension; poorly controlled diabetes; preoperative emesis < 6 hours before surgery

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Interventions

Intervention characteristics

Ondansetron

- *Dose*: 8 mg
- *Time point of administration*: 30 minutes before reversal of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: ondansetron 8 mg IV

Notes	Two out of 3 groups relevant (lidocaine group)

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Quote: "by use of sealed envelopes, patients were allocated randomly to one of three groups" Judgement comment: insufficient information on random sequence generation provided
Allocation concealment (selection bias)	Unclear risk	Quote: "by use of sealed envelopes, patients were allocated randomly to one of three groups" Judgement comment: not stated; "sequentially numbered, opaque, and sealed envelopes (SNOSE)"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "an independent anesthetist prepared the solutions, and the investigator did not know the contents of the solutions"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "another independent clinician, unaware of the group to which the patients had been allocated, assessed the level of pain on injection of propofol. The patients were asked a standard question"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Quote: "the study included 150 patients" Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	Unclear risk	Quote: "the demographic data were comparable among the three groups (Table 1)"

- *Type of general anaesthesia*: inhalational anaesthesia (desflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 140
- *Use of perioperative opioids (if yes, which?)*: 8 µg/kg/h to 15 µg/kg/h remifentanil, 50.0% treatment with opioids (piritramide)
- *Type of surgery*: vitreoretinal surgery

Dolasetron

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 80
- *Received treatment (n)*: NA
- *Analysed (n)*: 74
- *Age (mean ± SD, median (IQR), median (range))*: 64 (57 to 72)
- *Weight (mean ± SD, median (IQR), median (range))*: 71 (66 to 81)
- *BMI (mean ± SD, median (IQR), median (range))*: 26.0 (23.4 to 27.7)
- *ASA I/II/III/IV (n)*: 18/39/19/0
- *Gender (female in %)*: 52.6
- *Non-smoker (%)*: 71.1
- *History of PONV/motion sickness (%)*: 23.7/11.8
- *Type of general anaesthesia*: inhalational anaesthesia (desflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 150
- *Use of perioperative opioids (if yes, which?)*: 8 µg/kg/h to 15 µg/kg/h remifentanil, 48.7% treatment with opioids (piritramide)
- *Type of surgery*: vitreoretinal surgery

Droperidol + dolasetron

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 80
- *Received treatment (n)*: NA
- *Analysed (n)*: 76
- *Age (mean ± SD, median (IQR), median (range))*: 65 (55 to 73)
- *Weight (mean ± SD, median (IQR), median (range))*: 76 (71 to 85)
- *BMI (mean ± SD, median (IQR), median (range))*: 25.7 (22.8 to 29.9)
- *ASA I/II/III/IV (n)*: 17/40/19/0
- *Gender (female in %)*: 51.3
- *Non-smoker (%)*: 77.6
- *History of PONV/motion sickness (%)*: 22.4/14.5
- *Type of general anaesthesia*: inhalational anaesthesia (desflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 155
- *Use of perioperative opioids (if yes, which?)*: 8 µg/kg/h to 15 µg/kg/h remifentanil, 51.3% treatment with opioids (piritramide)
- *Type of surgery*: vitreoretinal surgery

Included criteria: ASA I to III patients undergoing vitreoretinal surgery

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Eberhart 2004 *(Continued)*

Excluded criteria: receiving antiemetics or long-term corticoid treatment, having nausea or vomiting during the 2 weeks before surgery

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Interventions	**Intervention characteristics** Placebo • *Dose*: saline • *Time point of administration*: 15 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 37.2% (dimenhydrinate 0.5 mg/kg) Droperidol • *Dose*: 10 µg/kg • *Time point of administration*: 15 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 22.4% (dimenhydrinate 0.5 mg/kg) Dolasetron • *Dose*: 12.5 mg • *Time point of administration*: 15 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 28.4% (dimenhydrinate 0.5 mg/kg) Droperidol + dolasetron • *Dose*: droperidol 10 µg/kg, dolasetron 12.5 mg • *Time point of administration*: 15 minutes before end of surgery • *Route of administration*: IV • *Rescue antiemetics (if yes, which?)*: 18.4% (dimenhydrinate 0.5 mg/kg)
Outcomes	*Vomiting (0 to 24 hours)* • Outcome type: dichotomous outcome *Nausea (0 to 24 hours)* • Outcome type: dichotomous outcome *Complete response (no PONV) in 24 hours* • Outcome type: dichotomous outcome *Arrhythmia (0 to 24 hours)* • Outcome type: dichotomous outcome *Extrapyramidal symptoms (0 to 24 hours)* • Outcome type: dichotomous outcome *Headache (0 to 24 hours)* • Outcome type: dichotomous outcome *Adverse events (general notes in the publication, 24 hours' observation)*

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "two sets of sealed envelopes were used for females and males, respectively, to ensure a homogenous gender distribution between the groups" Quote: "the patients were stratified according to gender to receive 1 of 4 prophylactic antiemetic treatments in a double-blind manner 15 minutes before the end of surgery" Judgement comment: randomized using sealed envelopes
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement on opaque, sequentially numbered envelopes (SNOSE)
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "the syringes were prepared by a third, neutral person not involved in the perioperative care of the patient, immediately before the start of anesthesia"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "the patients were visited on the ward 2, 5, 8, and 24 hours postoperatively by a blinded observer"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: dropouts < 15%, balanced between arms, reasons unrelated to outcomes of interest
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Eberhart 2004 *(Continued)*

Other bias	Low risk	Quote: "the biometric data (Table 2) and anesthetic and surgical parameters (Table 1) of the remaining 151 patients showed no relevant difference among the groups" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness, perioperative opioids): no

Eberhart 2006

Ondansetron + dexamethasone (8 mg group)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 30
- *Received treatment (n)*: NA
- *Analysed (n)*: 30
- *Age (mean ± SD, median (IQR), median (range))*: 42 (28 to 59)
- *Weight (mean ± SD, median (IQR), median (range))*: 71 ± 9
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 22/3/0/0
- *Gender (female in %)*: 84
- *Non-smoker (%)*: 60
- *History of PONV/motion sickness (%)*: 16.67/23.33
- *Type of general anaesthesia*: Inhalational anaesthesia (isoflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 106
- *Use of perioperative opioids (if yes, which?)*: 5.6 µg/kg intraoperative fentanyl, 56.3 mg postoperative nalbuphine
- *Type of surgery*: laparoscopic cholecystectomy

Ondansetron + dexamethasone (16 mg group)

- *Assessed for eligibility (n)*: -
- *Enrolled (n)*: -
- *Randomized (n)*: 30
- *Received treatment (n)*: NA
- *Analysed (n)*: 30
- *Age (mean ± SD, median (IQR), median (range))*: 43 (25 to 60)
- *Weight (mean ± SD, median (IQR), median (range))*: 72 ± 10
- *BMI (mean ± SD, median (IQR), median (range))*: NA
- *ASA I/II/III/IV (n)*: 20/5/0/0
- *Gender (female in %)*: 88
- *Non-smoker (%)*: 53.33
- *History of PONV/motion sickness (%)*: 16.67/20
- *Type of general anaesthesia*: Inhalational anaesthesia (isoflurane, N_2O)
- *Duration of anaesthesia or surgery (in min; as mean or median)*: 100
- *Use of perioperative opioids (if yes, which?)*: 5.7 µg/kg intraoperative fentanyl, 54.7 mg postoperative nalbuphine
- *Type of surgery*: laparoscopic cholecystectomy

Included criteria: undergoing general anaesthesia for elective laparoscopic cholecystectomy

Excluded criteria: received opioid, non-steroidal anti-inflammatory drugs, steroids, or antiemetic agents during the week before surgery

Pretreatment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness): no; (perioperative opioids): yes (use of nalbuphine was stated as similar among groups, but Group P 39.4 mg vs Group OD16 20.1 mg at 24 hours -> difference of about 50%)

Interventions

Intervention characteristics

Placebo

- *Dose*: saline
- *Time point of administration*: before induction of anaesthesia

Copyright © 2020 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Elhakim 2002 *(Continued)*

- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 30%; metoclopramide 10 mg IV

Ondansetron

- *Dose*: 4 mg
- *Time point of administration*: before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 17%; metoclopramide 10 mg IV

Ondansetron + dexamethasone (2 mg group)

- *Dose*: ondansetron 4 mg, dexamethasone 2 mg
- *Time point of administration*: before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 17%; metoclopramide 10 mg IV

Ondansetron + dexamethasone (4 mg group)

- *Dose*: ondansetron 4 mg, dexamethasone 4 mg
- *Time point of administration*: before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 7%; metoclopramide 10 mg IV

Ondansetron + dexamethasone (8 mg group)

- *Dose*: ondansetron 4 mg, dexamethasone 8 mg
- *Time point of administration*: before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 0%; metoclopramide 10 mg IV

Ondansetron + dexamethasone (16 mg group)

- *Dose*: ondansetron 4 mg, dexamethasone 16 mg
- *Time point of administration*: before induction of anaesthesia
- *Route of administration*: IV
- *Rescue antiemetics (if yes, which?)*: 1%; metoclopramide 10 mg IV

Outcomes

Vomiting (0 to 6 hours)

- Outcome type: dichotomous outcome

Vomiting (12 to 24 hours)

- Outcome type: dichotomous outcome

Headache (0 to 24 hours)

- Outcome type: dichotomous outcome

Adverse events (general notes in the publication, 24 hours' observation)

- Outcome type: general notes on side effects

Notes	None

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "allocated randomly to one of six groups (n = 30 each) using a computer-generated random number table"
Allocation concealment (selection bias)	Unclear risk	Judgement comment: no statement
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Quote: "study medications were prepared by a single nurse anesthetist in two identical syringes with 2 mL of solution to ensure blinding"
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Quote: "all nurses were blinded to the study groups"
Incomplete outcome data (attrition bias) All outcomes	Low risk	Judgement comment: no missing outcome data
Selective reporting (reporting bias)	Unclear risk	Judgement comment: no reference to a study protocol or trial registry number reported
Other bias	High risk	Quote: "patients' characteristics, factors related to operation and anesthesia, and simplified Apfel score, 12 did not differ between groups (Table I)" Judgement comment: baseline characteristics (age, weight, ASA): no. Potential effect modifiers (gender, duration of anaesthesia, non-smoker, history of PONV/motion sickness): no; (perioperative opioids): yes
